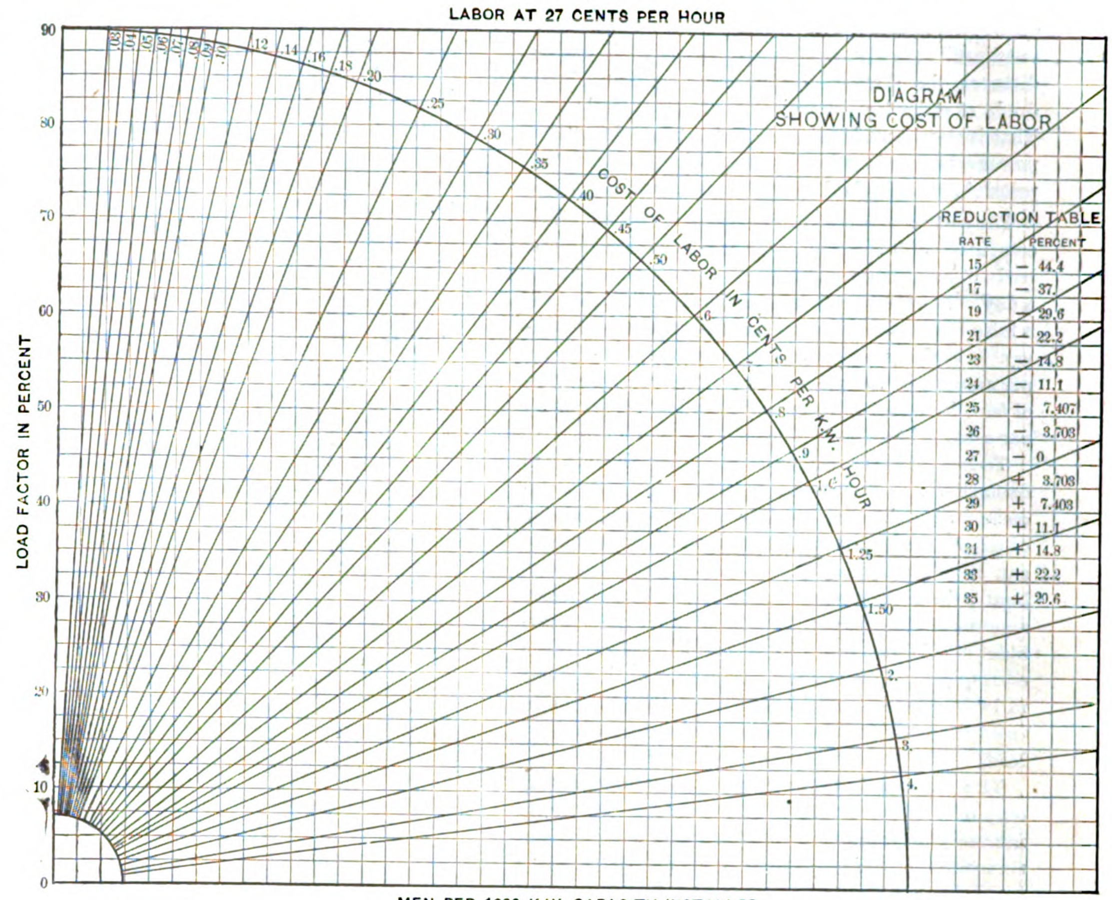
To further illustrate the use of this diagram, let us consider that the equipment of our standard station is cut into so many units that it required 3.7 men instead of 1.94. Price of labor and load factor being 27 cents and 33.3 per cent. respectively, 3.7 followed on the diagram up to 33.3 per cent. gives .3 of a cent, as against .157 cent for standard.

The cost of fuel is the next item to be considered in the operating expenses of the standard station. Considering coal as the fuel used, its cost per KW. hour depends on the price per ton and on the efficiency of the station, which is best expressed in pounds coal consumption per KW. hour. The coal for standard station I have assumed to be clear bituminous, costing $3 per short ton delivered.

As to the efficiency, I am able to quote from tests in which I was personally engaged on a station of the same size and similar equipment. The duration of the test was forty-five hours, made under actual conditions of railroad service during the day, and at night the load was kept on the station by means of a water rheostat. I will say here, however, that the test on the steady night load did not show any great gain in efficiency, due to the fact that the day load of the station was steadied by feeding in with others. The average efficiency of transformation IHP. to EHP. at the switchboard was 90 per cent. The steam consumption of the engines was 14.5 lbs. per IHP. hour. This record on a later test has been lowered. The boiler evaporation was 9.4 lbs. water per lb. of coal from actual conditions. The coal used was New River bituminous. The economy of the station, represented by the coal consumption in pounds per KW. hour, was 2.3. I have assumed 2.2 for this figure for the standard station.

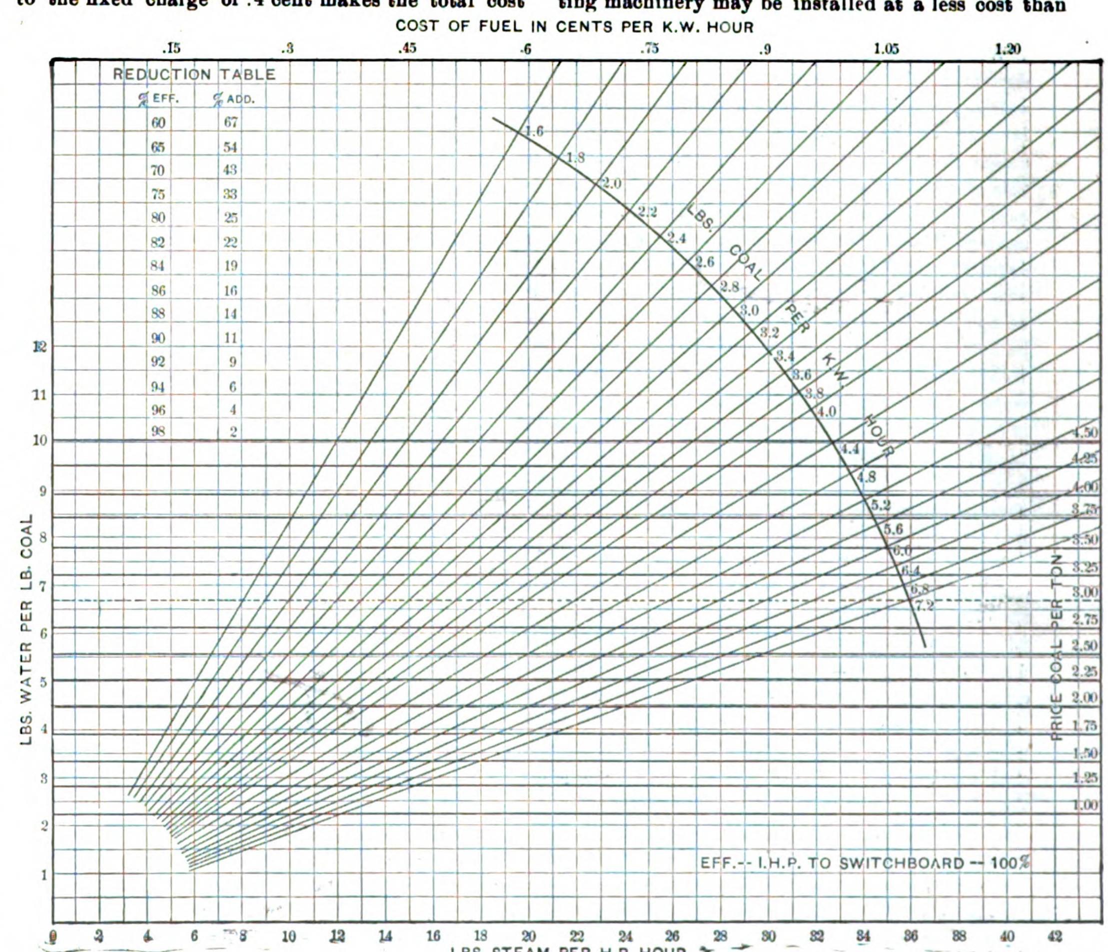
Reducing price per ton to price per pound and multiplying by 2.2 gives .33 cent as the cost of coal per KW. hour. This appears in Table No. 1 under cost of fuel. As an illustration of what the cost would have been had the engines required more steam, say 26.6 lbs. per IHP. hour, as might be the case with a non-condensing engine, referring to the fuel diagram and considering the electrical efficiency, boiler evaporation and price of coal to remain the same, 26.6 to 9.4 lbs. water per pound of coal gives 3.8 lbs. coal per KW. hour. Following this line down to horizontal $3 coal line and vertically upward from this point to cost of fuel in cents per KW. hour we obtain .57 cent, were the efficiency of transformation 100 per cent., but since it is assumed to be but 90 per cent., 11 per cent. has to be added to this cost, as shown in the reduction table. This gives the cost of coal per KW. hour .63 cent, as against .33 for the condensing engine.

There remains to be included in the operating expenses for this station, water, oil, small supplies, repairs, superintendence and general expense, which I



Street Ry. Journal

have estimated at .093 cent per KW. hour. The total operating expense foots up to .58 cent., which added to the fixed charge of .4 cent makes the total cost



Street Ry. Journal

power from standard .98 cent or very nearly one cent per KW. hour.

Before comparing the costs from the various steam plants I will review briefly the circumstances governing the production of power by water.

The application of water power to street railways has the following points of advantage: In plants operated under any but very low heads the generating machinery may be installed at a less cost than for steam. The fuel expense also disappears as well as a portion of the cost of repairs. A part of the labor expense will be saved, inasmuch as

no engineers, firemen or coal handlers are required The main disadvantage in the application of water power to street railway operation lies in the fact that generally railroad power stations are quite distant from waterfalls, and that it is very expensive to transmit the electrical energy to any considerable distance, the distance of transmission being hundreds of miles for the majority of street railways. That it may be made more profitable to employ water power when its location is nearby the road and the price of coal is high also, there can be no doubt.

The cost to produce power from water is often compared with the cost to produce from coal on the basis of continuous operation for twenty-four hours a day. For street railway service this method gives a false impression, since it implies that the machinery is working at its full capacity for 8,760 hours per annum, or 100 per cent. load factor; as a matter of fact, for street railway service a load factor of 33 per cent. is high.

To look at this from another point of view, the demand for power for street railways cannot be increased at will, as it may be in a manufacturing concern. In the latter, if it is found advisable to run night and day at full capacity, instead of ten hours, there is produced a correspondingly greater amount of the product, be it flour, steel rails or carbide of calcium, and this output is produced at a correspondingly decreased cost per unit. For street railway service, on the other hand, there has to be installed sufficient machinery to take the peak of the load.

This is usually three times the average, and is only of a few hours' duration each day. If it were necessary or profitable to use this full capacity continuously for other industries it would be possible to do this with very little increase of labor, no increase of fixed charges, and the additional expense of producing the greater output would be merely the coal and a slight increase of supplies and repairs. This combination is the feature of the Niagara work.

When the expense of transmission shall have been decreased by the successful employment of higher voltage, it will then become a problem as to whether it will not be profitable to produce power from a steam plant located at a coal mine, coal costing in this case but 80 cents a ton. This would bring the cost of fuel down to .12 cent per KW. hour, as against .33 cent for standard plant. Further, this expense would only continue for the comparatively small number of hours that the plant would have to be operated for street railway service. This might be better economy than to pay the fixed charges that would accrue from the expensive development of water powers at possibly much greater distances. It is to be noticed in this connection that the cost of installing the steam station would be considerably less when located at the coal mine, since it would then be unnecessary to equip with the most economical and expensive machines.

Water power produced in various parts of the country varies greatly in its cost. It is reported that the electrical energy so produced costs from $14 to $32 per annum per KW. continuous output. This expense is largely made up of fixed charges, which increase rapidly as the expense of making the necessary improvements is greater. The standard steam plant produces power with $3 coal for $29, and with 80 cent coal for $22 per KW. per annum, which compares very favorably with the above for water power.

A disadvantage occurring in the use of water power is that in some cases, on account of certain periods of low water, an auxiliary steam plant has to be kept in reserve, which is, of course, an additional expense. There can be no general rule given that will determine whether it is more advantageous to use water or steam power. Each case must be figured by a competent engineer and decided on its merits.

The great majority of street railways being operated by steam, I shall not dwell longer on water power, as there is considerable ground to be covered in the consideration of the steam stations. I have compiled and classified the data on representative ones throughout the country; Tables No. 1 and No. 2 give the results.

The general arrangement of the tables is as follows: Each vertical column contains the data for a different station during a stated period. Each station is represented by a number, which appears at the head of the column; only a portion of the table is exhibited to you on the large diagram, for obvious reasons, but I will describe the different items as they appear in the completed table. The first column is headed

S, for standard station; following down the column, first comes the capacity expressed in multiples of 1,000 KW., 3.6 meaning 3,600 KW. The number of units of engines 3, ditto for generators 3, number of units engine per 1,000-KW. capacity is .83, obtained by dividing 3 by 3.6; ditto for generators .83. The next line under type is a description as to whether the engines are belted or direct connected to the generators, *B* for the former and *D C* for the latter. The two lines marked *S C T* and *N* or *C* refer to engines, simple, compound or triple, non-condensing or condensing, as in standard *C C* is compound condensing.

The period during which the averages are taken is given in days. Load factor is in per cent. Inserted in the proper place under costs are the per cent, *S*, and per cent total, which figures represent the per cents the items bear to the corresponding ones for standard and to the total operating expense respectively.

The number of shifts, duration in hours and shift hours, together with the rate of pay of men in cents per hour and number of men per shift per 1,000-KW. capacity, complete the data necessary for the analysis of the cost of labor. Costs are all expressed in cents per KW. hour. Opposite fuel, pounds of coal per KW. hour and price, which is dollars per short ton, give the necessary figures to analyze the cost of fuel per KW. hour. Kind *A* or *B* refer to anthracite or bituminous.

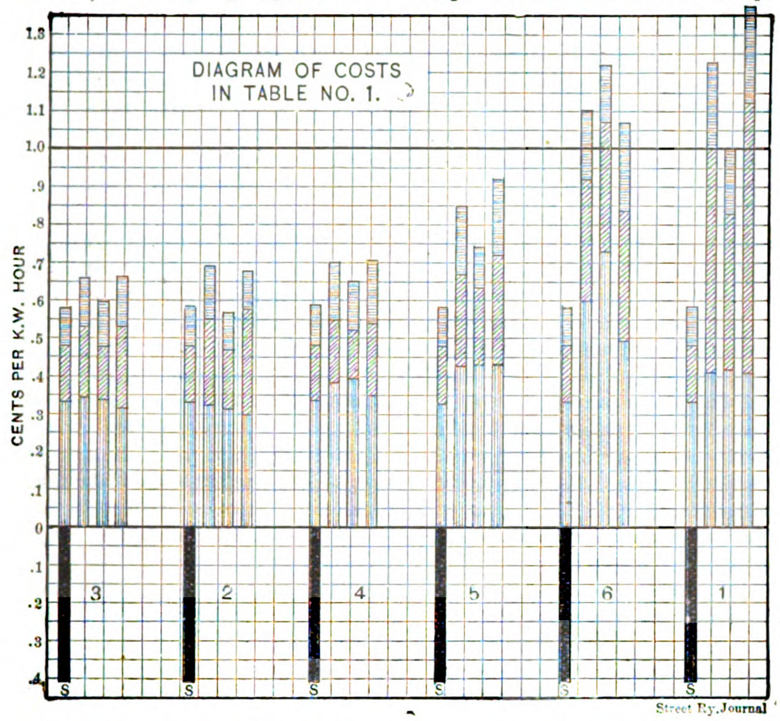
Repairs, supplies other than coal, that is, water, oil, waste, lamps and miscellaneous, as well as superintendence and general expenses, are treated as one item, hereafter called general expense.

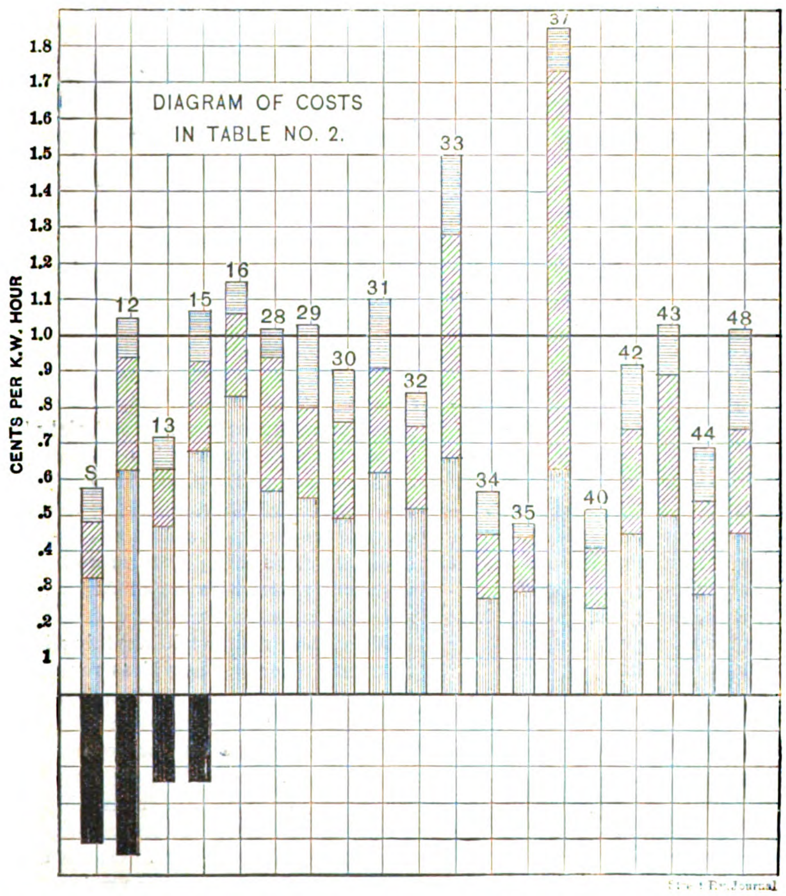
As a supplement to the tables, in order to more clearly illustrate the relation of the costs, I have constructed diagrams in which these are represented by different characters of lines as to shading.

It will be noticed that these shaded lines are of various heights, their height corresponding to the cost of power in cents per KW. hour. Three kinds of shading are used: horizontal, equaling the cost of coal; vertical, the cost of labor, and diagonal, gen-

eral expense. These, which are operating expenses, are laid out above the line, and black, equaling fixed charges, is plotted below the line. The distance from the base line 0 up to 1 represents 1 cent. and the magnitude of each item is denoted by the length of its shading. The diagram for Table No. 1 is laid out in six groups, one group for each station. The first or left hand column in each group represents the costs for the standard station. You will notice that its total length, including the black, is about equal to the distance between 0 and 1, so that, including fixed charges, the cost of power per KW. hour per annum for the standard station amounts to about 1 cent. It also appears that the fixed charges are approximately equal to the coal. Labor is roughly about half the coal, and general expense about half the labor. These proportions are easily remembered, and we might expect them to hold approximately for stations under similar governing conditions.

(*To be continued.*)





INSPECTION AND TESTING OF MOTORS AND CAR EQUIPMENTS BY STREET RAILWAY COMPANIES.*

BY F. B. PERKINS.

In discussing this subject I have decided to speak of inspection and testing separately. The work of inspection is to be attended to principally in the car houses, with a small amount of attention while cars are in service. The testing is to be done in the repair shop. In no direction can a railway company save money or increase dividends more rapidly than by having its equipments thoroughly inspected by competent men, working systematically under intelligent direction. After a car has been through the repair shop and is again placed in service it is naturally supposed to be in first-class condition. It comes then under the immediate supervision of one or more men, presumably the day and night foremen, whose duty it is to keep that car in good condition for so long a time with as little expense as is possible. These men should be thoroughly acquainted with every detail of that car. Instead of examining cars once in thirty or sixty days a daily inspection is necessary. I have thought it expedient for the purpose of setting forth my views on inspection to describe the work as being carried out in a modern car house containing fifty equipments, and arranged for the easy handling of the cars, so that no extra help will be required for that purpose.

In dealing with the inspection of cars in this car house, we believe better results can be obtained by giving to each man some particular branch of the work, rather than assigning to him a certain number of cars and expecting him to do all the work required thereon. For instance, it is safe to assume that the controllers will be kept in better condition if the responsibility of a good repair be placed with one man only than would be the case were this branch of the work made a part of the duties of several workmen in conjunction with all other repairs found necessary. If this be true in regard to controllers it will be found equally pertinent to all other items of car inspection. There is also this advantage—the men will carry the tools and material for one particular kind of work only, whereas if they had a multiplicity of duties to perform it would necessitate their having a large assortment of tools and material or wasting considerable time in going back and forth to the stock room.

In this modern car house five men will be required. This estimate includes only the repair men proper, and not the foreman of the car house, whose duties in connection with handling of motormen and conductors, sending out cars and similar work, would require so much of his time that he could only have a general knowledge of the work of inspection in the car house. Two of this number would be required to grease and inspect the motors; one to keep the controllers in repair, one to take care of the trolleys and to assist in the care of trucks and car bodies, one to have charge of the trucks and car bodies.

The most vital parts of the equipments are the different parts of the motor, viz., armatures, fields, bearings, brushes and brushholders. The care of this part of the equipments should come under the head of greasing, and on the manner in which this part of the work is done depends to a large extent the frequency with which the cars will break down while in service, and also the amount of repair necessary to keep them in operation. Oftentimes the most ignorant and cheapest men are given the place of greaser. On the contrary it is a position where intelligence and thoroughness are imperative. In order that he may have sufficient time for thoroughness in detail, he should not be expected to ring alarms or attend to other matters of a miscellaneous nature, but should be held responsible for his own particular work.

The car should pass into the greaser's hands the first day after it is on the road and every second day thereafter. He should examine thoroughly brushes, brushholders, gears, pinions, bearings and commutator. Of these parts the care of the bearings and commutator is the most important, and should therefore receive the greatest amount of attention. The manner of caring for the bearings is very simple. They must be well supplied with grease or oil, and care must be taken that they are kept free from dust and grit, and also that the grease feeds properly.

In the matter of the care of commutators, electricians seem divided in their opinion as to whether they should be sand-papered or not; personally, I am not in favor of it. Instead of temporizing the commutator by sand-papering it, and thereby simply putting it in shape for one more day's work, I would get at the bottom of the trouble, and either make a

* Read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

commutator, by some preparation of mica and copper, which will not spark, or if the trouble lies deeper, remedy it by remodeling the entire motor. This may seem to be a heroic measure, but the end will justify the means. I think, however, that usually the trouble is not in the commutator, nor with the motor, but in either the brushes or brush-holder, or both, and it is probable that with proper adjustment and with proper care and treatment we should find the trouble obviated and sand-papering of commutators unnecessary. When speaking of the treatment of brushes we refer to a treatment of oil or something similar.

The writer has personal knowledge of a large road where common brushes were used without any treatment or care except to replace them as needed, and it seemed as if the man who used the most brushes was given the credit of taking the best care of his motor. The average life of brushes on this road and the above conditions with the commutator sand-papered every day was six days. Subsequently the sand-papering was stopped entirely, and the brushes were removed every six days and properly treated in oil. The life of brushes under this treatment was increased from six days to from forty to sixty days. The trouble with commutators, which before had been great, was reduced to a minimum, in fact, almost entirely averted. It is possible that under some heavy conditions the practice of sand-papering must be kept up, but it must be accomplished in a different manner, and, instead of indiscriminate sand paper, it must be applied sparingly.

Not later than every fourth day every controller and switch comes under the notice of the man who has charge of those parts. The main point is to clean thoroughly, using a little vaseline on the contacts. The parts that are worn should be touched up with a file, or should be sand-papered, and if badly worn should be replaced, so that at least every fourth day the controllers will be sent out in first-class condition. This man can also examine the car wiring, lamp fixtures, headlights and all similar parts.

The fourth man will have the care of the trolley poles and wheels. These should be carefully looked over each night and oiled if necessary. The man who attends to this part of the equipment will also have considerable time to devote to general inspection of the car bodies and trucks under the direction of the general inspector. Under the scrutiny of these two men should come all the details of the car body, such as grab handles, window catchers, curtain fixtures and similar parts. These should be carefully attended to each day, insomuch as the reputation of the road will suffer in direct proportion as the attention to these small details is neglected. For the public is exceedingly exacting as regards the manner in which its comforts are catered to in these minor details, and the degree of excellence which characterizes this part of the work will be largely instrumental in molding and fashioning its opinion of the road and of its servants in management.

The matter of car cleaning will not be considered in this paper, as it is not directly connected with the subject in hand.

After having touched upon the subject of the matter of inspection in the car house we have to deal with outside inspection, that is, inspection on the road by inspectors, motormen and conductors. It may be a good plan to have outside inspection, and it is often advantageous, if not carried too far, but I do not believe it is desirable to have a large force, for this reason, but very little of the time devoted to this line of inspection is really used in looking over the equipments, but must necessarily be consumed in getting from one car to another and in waiting for opportunities, and most of the trouble located by these inspectors is not of such a nature as to require immediate attention. If it were, the inspector could not make the necessary repairs without taking the car to the car house.

Troubles of a serious nature, such as would require immediate attention and taking the car out of service, should be easily detected by the motorman or conductor, and reported at once to the proper official. It may not be entirely irrelevant to speak here of the relation of motormen and conductors to the inspection of cars. It has been proven that it is usually a waste of time and very little has been accomplished by attempting to instruct motormen and conductors in other than the simplest ideas of electrical problems, for while on some roads there may be a number of old motormen who have a fair idea of electrical equipments, and whom it would probably be safe to allow to locate existing trouble, it would be difficult to draw the line between the men competent in this direction and those wholly lacking in such knowledge. I know of nothing more distasteful to passengers unwillingly detained than sitting in a car impatiently waiting while a motorman works over some part of the equipment in a vain endeavor to locate some trouble, the very nature of which he has not the faintest idea, and quite likely, at the same time, interfering with the movement of several other cars.

Of course, contingencies might arise where men would be justified in attempting to locate trouble on their cars, but as a rule they should not be allowed to do so, as the practice is wrong. If they clearly understand the brake mechanism, the right manner in which to apply the power to the motors, how to use the cut-out switch in the controller, and have a clear conception of the general rules as promulgated by the company, this will be about as far as it is profitable to teach them.

But while we may not allow them to make repairs or experiment with the equipment we must educate them to the necessity of being able to immediately detect any unusual or threatened condition, and to at once report the same. In fact, they must be made to feel that it is their first duty to report everything that is working to the possible detriment of the company, and if we properly impress them with the importance of these details as outlined above we shall have established a means of quickly locating trouble on the road, and that without the aid of special inspectors.

Next comes the matter of testing. The service which we will obtain from our equipments depends largely upon the manner in which the repairs are made. If the repair work be rushed through with the idea of going over as many cars as possible in a short space of time, and with little or no regard for the thoroughness of the work, we must expect the necessity for repairs to increase to an alarming extent. If, on the other hand, we make our repairs with the idea that work thoroughly done will have a tendency to greatly decrease the liability to break-downs while the cars are in service, and correspondingly reduce the amount of work to be done in the repair shops, we shall naturally consider the best means not only of doing the work, but of definitely determining its condition when finished. To do this properly we must resort to our testing, and we use the word "testing" in a broader sense than it usually signifies. For example, all material furnished, such as tape, mica, paper, etc., must be kept up to the standard, and to accomplish this everything used should be carefully examined, or, under our classification, tested.

We must begin testing in the purchasing department. In the purchasing of supplies a great deal of trouble is often occasioned by changing the kind of material furnished. This is probably more noticeable in the case of small roads. Now, while there may be no great difference in the quality of goods furnished, or if any one of the many different kinds were used exclusively, it would give satisfaction, yet the very fact that many different kinds are used has a tendency to produce a lack of carefulness in the details of the work which will almost invariably show in the general result. This will be noticeable in several ways. The workmen will take one of the following views of the matter. He will either think the management is careless in the matter, and as a consequence he will immediately commence to drop from the former high standard of work, or he will think that there is nothing essential about the quality of the material used, and acquire the pernicious habit of utilizing anything which may happen to be handy.

When a workman once detects what seems to him to be a lack of thoroughness in any part of the work which has to do with his department, you have at that moment allowed to enter that department a spirit of carelessness which will develop very rapidly and unless quickly suppressed will produce disastrous results in a short time.

To attain to a condition of thoroughness in any line of work may have called for the performance of a great deal of hard labor, the expenditure of much time and money, and the exercise of patience, skill and forethought, but how slight a relaxation of vigilance on the part of some official trusted with the maintenance of the good condition acquired can undo in an incredibly short space of time the good work accomplished, and cause a retrograde movement along lines which had promised so favorably.

If, however, we have to allow only one kind of material in the repair shop, the question naturally arises as to how we can avoid being behind the times in the matter of different kinds of supplies, and also in the manner of their use. The answer is, we must have an experimental room, and here must be tested samples of all supplies and material before being contracted for by the purchasing agent. I do not mean to say that this room must necessarily be separate from the repair shop, as this would naturally require a large amount of machinery which we already possess and would not care to duplicate. But this room must be considered by the employes as one in which they are not directly interested other than as they are required to work on some portion of that which is being tested, but the special testing and all the instruments for the same must be in a separate department, and if it is not possible to have a separate room, at least a part of the repair shop should be partitioned off for this work, as the amount of time wasted by the employes of the shop attracted from their regular duties by the testing of some part of equipment or material on the floor of the repair shop proper, would, if saved, more than compensate for the expense incurred in the creation and maintenance of such a room.

Having thus arranged this separate apartment for practically all testing purposes, and having impressed upon employes and workmen that herein will be settled all questions relating to work done and material used, we have accomplished one of the results aimed at, in that we have prepared ourselves to impress upon the men that any material placed in their hands for use in repairs has previously been thoroughly tested, and this, we think, will tend to raise the standard of work, as any results of poor workmanship on their part cannot then be laid to faulty material. This will give them an incentive to conscientiously deal with established and known good material.

We are now able to take anything in the line of new material or any new ideas regarding the use of the same, or any electrical problems which may arise, and ascertain their value without interfering in any way with the regular work of the shop or of the employes.

It is neither necessary nor desirable that the workmen should know the merits or defects of whatever comes to the testing room. On the contrary, there are some of the employes who should be allowed to become familiar with a great deal of the work of this room. They will not only be more valuable for the knowledge thus obtained, but some of the work must of necessity be delegated to some other person than the electrical engineer. But at all times it must be made plain to them that the room is dis-

tinctly a separate department, having no connection with their ordinary work.

Having now provided for our testing department and established its relation to the purchasing of supplies and to the employes of the repair shop, what machines and instruments shall we need in its equipment?

A high and low reading direct-current voltmeter, one having a double scale reading from 1 to 750 and from 1 to 15.

A direct-current ammeter reading from 1 to 100.

A low reading ammeter would be very convenient many times, but is not absolutely necessary.

A 50,000-ohm magnetic bell.

An alternating current voltmeter and some handy testing set will make an outfit of instruments with which we can do all the testing required.

If the alternating current is not within reach of the car house we must procure a small dynamo, and produce it ourselves. A very small machine, say 2 HP., would be sufficient for all the needs of the testing department. If this machine is designed for about 100 volts it would be most convenient for our use. With a few small transformers wound for 2,000 volts primary and for either 50 or 100 volts secondary we are prepared to furnish any voltage within a range of from 5,000 to 10,000 volts.

The man who has this part of the work in charge can very easily and cheaply arrange the details of installation of the wiring, etc. He can also make some resistance coils and many other pieces of apparatus which will greatly facilitate the quick testing of whatever may be sent to this department.

What shall we test? First, everything that goes into the repair shop. By doing this we shall be sure of keeping all material up to the standard, which means an absolute guarantee against breakdowns caused by poor material. In this way we raise the standard of workmanship.

Second, all supplies which go to the foremen of the car houses. In connection with this matter we are of the opinion that in the testing room should be decided the manner of treating brushes, the length of time they should be used before being removed from the motor, the manner in which they should then be cared for, their final disposition, the proper attention to be given the trolley poles, the length of time they ought to remain in service, their condition when removed, and many other similar questions should not be left to work out their own solution or dependent upon the feelings or judgment of the various employes and workmen, but should be definitely determined and decided in our testing department.

Many may be of the opinion that we are carrying system beyond necessary limits in thus definitely and positively arranging these details, but why should we allow several different men to use material in whatever manner they may individually see fit, to treat brushes as their fancy may dictate, to regulate the tension of trolley poles in accordance with their own feeling at the time rather than by any fixed standard, and various other matters which might be mentioned along these lines?

Third, all finished material, such as armature coils, insulation for controllers, commutators and brush-holders. We do not necessarily need to test every piece, but enough to satisfy ourselves that the general order of work is kept up to the standard.

Fourth, all armatures, fields, commutators and controllers, as they are being made or repaired. One illustration will be sufficient to show how the testing may be carried on in this branch of work.

An armature is wound and ready to be connected to the commutator. With a small wire we connect all of the top leads together, with the bottom leads each separate from the other. With a magneto or testing set we find the insulation of the complete armature is not right. First we cut the small connecting wire on the top leads in several places, then by testing each of these parts we locate that portion of the armature which is bad; then by removing the wire we will test each coil separately until we find the weak one. Next, by the use of our transformers we obtain 3,000 or 4,000 volts, which we apply to this one coil. If it stands the test we may allow it to go through, and if not, it can be replaced. If we should find that the trouble extended to a large portion of the armature and indicated moisture in the coils, we may, by the use of this same transformer, obtain 25 or 30 volts, and by connecting the armature to the commutator with the exception of one end of one coil, then connecting one side of the 25-volt circuit to this end, and the other side of the circuit to the commutator or bar left vacant, we may apply the current for the purpose of drying the armature. With this advantage the heat will be generated in the core, and the armature will dry from the inside instead of from the outside.

With similar tests on all finished parts sent out from our repair shop we have almost wholly removed the chances of failure in service, and have unquestionably added to the length of life which may reasonably be expected from our equipment.

By running a few wires from our testing room to that part of the shop where the cars are brought in for repairs we are able to reach every part of the equipment in a quick and thorough manner, and it is probable that if a few tests are made on every car that comes to the shop many troubles will be located before they have sufficiently developed to become serious. Hence, the time required to make tests will add nothing to the pay roll, while the benefits derived may be many. All cars should be brought to the repair shop, thoroughly overhauled and inspected at least twice a year.

In determining what shall be the standard of the work in the different branches of the shop, or finished material, and of cars in service, I do not believe there can be any fixed scale. But that, as we proceed with our testing and inspection, we shall gradually raise the standard of our work, and it will only be a short time after adopting a thorough method of doing the work that many of the daily perplexities will have been eliminated.

The New President.

Charles Spencer Sergeant, the new president of the American Street Railway Association, was born in Northampton, Mass., in 1852. His father was born in Stockbridge, Mass., which has been the family home since the settlement there in 1735 of his great-great-grandfather as a missionary to the Stockbridge Indians. The new president was educated in the public schools of Northampton and was graduated from the high school in 1868. In that year he began his business career in the employment of the First National Bank of Easthampton. In 1872 he entered the steam railroad business as paymaster and cashier of the Marquette, Houghton & Ontonagon Railroad Company and was also associated with various iron companies and engaged in the iron smelting business. In 1876 he went to Boston to take the position of chief clerk of the Eastern Railroad Company, subsequently being appointed general auditor. In December, 1887, when the West End Street Railway Company came into possession of the several street railways centering in Boston, he was offered and accepted the position of general auditor of the company, subsequently being made second vice-president, and in November, 1892, he was appointed general manager of the West End, which position he held until its lease to the Boston Elevated Railway Company, of which company he is now second vice-president.

It will be seen from the record here given that Mr. Sergeant is well equipped for his new position as far as practical experience in street railway and business matters is concerned, and his personal merits are so well known in the Association that we need not refer to them further than to say that he is held in high esteem by the members.

THE FIRST ELECTRIC MOTOR.

Editor ELECTRICITY.

Permit me to further elucidate and correct an article copied from the Chicago *Record* respecting the first electric motor, in which an "out" was plainly apparent. It said the electric motor was the invention of Thomas Davenport, "an ordinary blacksmith, going to perform with the force and energy wrapped up in galvanic magnetism. Ignorant of mechanics he enlisted the aid of Andrews and Smalley, both practical machinists, and the latter the inventor and maker of an automatic machine for cutting the screw threads on nuts and bolts."

As stated above, Mr. Davenport was a common blacksmith at Brandon, Vt. In December, 1833, he went to Crown Point, on Lake Champlain, to get iron for use in his shop. There he saw for the first time an electro-magnet which was in use at the Iron Works for extracting iron from pulverized ore. Though it weighed but four pounds it would suspend a weight of one hundred and fifty pounds. It attracted his earnest attention. Though he had never heard of such a thing, he instinctively saw in it force and energy. He purchased it instead of the iron he went after, took it home, declaring to his neighbors, amid their jeers, that from it he could get power enough to move the largest boats on the lake. He abandoned his forge, and with the aid of Andrews and Smalley, for he did not know the name of a single part of the apparatus, he succeeded the following year in perfecting rotary motion and a motor.

It was in 1836, if memory is correct, that Mr. Andrews (not Mr. Smalley) at the Iron Works, Forest Dale, three miles from Brandon, invented a machine for cutting the threads on bolts and nuts and making the heads on bolts automatically, and the machines were in constant use there. No patent was secured for it and it became of common usage.

In my former article it was stated that while Davenport was developing his motor he and Smalley ran a wire between their residences, over which they sent and received messages. Is it not possible that herein lies the actual discovery of the electric telegraph or the telephone? Whether they used a system of sounds to signify words, or a diaphragm, cannot now be determined. L. F. ANDREWS.

Des Moines, Iowa, Sept. 11.

Prof. R. B. Owens' Successor.

The friends of Mr. Morgan Brooks of Minneapolis will be pleased to learn that he has been appointed Professor of Electrical Engineering in the University of Nebraska, at Lincoln, to succeed Prof. R. B. Owens, who has accepted a professorship in McGill University, Montreal. Mr. Brooks is a graduate of Brown University, class of '81, and of Stevens Institute, class of '83, and is well qualified in every respect to fill his new position. The Electrical Engineering Company of Minneapolis, of which Mr. Brooks is president, will not be affected by his appointment, as he will retain his interest in that company and remain its president.

The Street Railway Accountants' New Officers.

The following are the officers elected for the ensuing year by the Street Railway Accountants at their recent meeting in Boston:

President—J. T. Calderwood of Minneapolis.
First Vice-President—E. R. Tighe of New York.
Second Vice-President—R. S. Williams of Richmond, Va.
Third Vice-President—F. E. Smith of Lynn, Mass.
Secretary and Treasurer—W. B. Brockway of Toledo, O.
Executive Committee—H. L. Wilson of Boston, chairman; H. E. Babcock of Elmira, N. Y., H. O. Mackay of Milwaukee, and J. N. Fraser of Ottawa, Can.

The Association decided on Chicago for its next annual meeting, which will be held simultaneously with that of the American Street Railway Association.

ANNUAL MEETING OF THE STREET RAILWAY ASSOCIATION OF NEW YORK.

The sixteenth annual meeting of the New York Street Railway Association was held at Manhattan Beach Hotel, Coney Island, on Tuesday and Wednesday of last week. About thirty electric railways, whose capital stock would aggregate probably $300,000,000, were represented, and a large number of supply men were on hand to show the magnates and managers how to augment their dividends and the efficiency of their lines by the adoption of whatever apparatus or appliance they were there to extol.

The President of the Association, G. Tracy Rogers of Binghamton, in his opening address complimented the Executive Committee for the manner in which they had conducted the affairs of the Association during the past year, and spoke at length on the progress made in improving the street railways throughout the State. He referred particularly to the changes made in New York City, and alluded to the rapid construction of lines in the metropolis as a noticeable feature in street railway history.

The papers presented at the opening session were: "Signal System for Single Track Railroads," by H. S. Cooper of Schenectady; "By-Products at Power Stations," by Dr. H. M. Fenner of Fredonia; "Track Building," by R. P. Brown; "How to Develop New Traffic on Street Railroads," by H. Milton Kennedy of Brooklyn. The latter paper was listened to with close attention and was followed by an interesting discussion which was participated in by several members.

Mr. Koran Sugahara, of Japan, who produced such a favorable impression by his remarks at the Street Railway Convention in Boston, was introduced to the delegates and made a brief speech in which he detailed what had been done in the railway line in his own country, and pointed out the advantages Japan offered for American enterprise.

In the evening, after the visitors had witnessed the "Fall of Manila" and Pain's fireworks, the delegates and their guests sat down to a banquet in one of the large rooms of the Manhattan Beach Hotel and had a merry time, Tom L. Johnson acting as toastmaster. Among those who were called on to speak was President Vreeland of the Metropolitan Street Railway, whom the toastmaster referred to as "the embodiment of sixteen railroad presidents in one," alluding to the number of companies that had been absorbed by the Metropolitan. Several of the toasts were responded to in a witty manner and the whole affair was as pleasant as one could wish.

The reception committee consisted of Clinton L. Rossiter, president of the Brooklyn Heights system; Albert L. Johnson, president of the Nassau system, and John L. Heins, president of the Coney Island Railroad.

On the 14th the Association elected officers, visited the Navy Yard, Brooklyn, and were treated to a sail around the harbor on the steamer Hudson, an elaborate luncheon being served on board.

The officers elected for the ensuing year are:

President—G. Tracy Rogers, Binghamton (re-elected).

First Vice-President—W. Caryl Ely, Niagara Falls (re-elected).

Second Vice-President—Albert Johnson, Brooklyn.

Secretary and Treasurer—Henry A. Robinson, New York (re-elected).

Executive Committee—H. H. Vreeland, New York; John W. McNamara, Albany; Henry M. Watson, Buffalo; Clinton L. Rossiter, Brooklyn.

It was decided to hold the Convention next year at Ithaca.

The American Electro-Therapeutic Association.

The Eighth Annual Convention of this Association was held at Buffalo on the 13th, 14th and 15th inst. Several important papers were read at the meeting, all tending to show that the use of electricity, especially in surgical operations, is proving of incalculable benefit both to the practitioner and the patient, and is being introduced into almost every branch of surgical practice. Alluding to this, the president of the Association, Charles R. Dickson, said: "One has but to glance at the programme to see to what extent electricity may be used, and used to advantage. A programme such as ours should prove a perfect revelation to him who has not kept well up to this progressive age."

Some amendments were made in the constitution and by-laws of the Association.

On the evening of the 14th Dr. Lucien Howe gave a reception to the members at his home in Buffalo, and on the following day they enjoyed a steamboat excursion down the river and a dinner at the Island Club House.

The following officers were elected:

President—Dr. Francis B. Bishop of Washington, D. C.

First Vice-President—Dr. Ernest Wende of Buffalo.

Second Vice-President—Dr. W. H. White of Boston.

Secretary—Dr. John Gerin of Auburn, N. Y.

Treasurer—Dr. Richard T. Nunn of Savannah, Ga.

Executive Council—Dr. Robert Newman of New York and Dr. G. Belton Massey of Philadelphia, three years; Dr. A. D. Rockwell and Dr. William J. Morton of New York, two years; Dr. Charles R. Dickson of Toronto and Dr. Frederick Shavoir of Stamford, Conn., one year.

The next annual meeting will be held in Washington, D. C., on September 19, 20 and 21, 1899.

LEGAL NOTES.

Where one was killed by stepping on a charged electric wire, which was broken in two and lying on the ground in an alley, the electric light company was held by the Supreme Court of Missouri to be *prima facie* negligent and liable. Gannon vs. Laclede Gaslight Co.

A city which has permitted an electric street car company to occupy its streets for five years without objection cannot thereafter object. State vs. Spokane St. Ry. Co., Wash. S. C., 53 P. 719.

The fact that a wire charged with a dangerous current of electricity fell and caused injury is held by the West Va. Supreme Court to make a *prima facie* presumption of negligence, but not a conclusive one, as the misfortune may have occurred from unavoidable accident.

The Indiana Supreme Court decides that a telephone system may be owned and controlled by an individual person, notwithstanding the grant by the Legislature of such rights to corporations. An individual may conduct any proper business without Legislative assent, unless there has been some Legislative restriction upon such right.

A decree pro confesso was entered at Galveston, Tex., on the 5th inst., against the Citizens' Electric Light Company for failure to answer to the complaint in the suit brought by the Massachusetts Loan & Trust Company.

The Electric Storage Battery Company of Gloucester, N. J., has filed in the United States Court at Wilmington, Del., a petition asking for an injunction to restrain the Wilmington City Electric Company from putting in its proposed storage battery plant. The Storage Battery Company alleges that the Wilmington concern is infringing on patents it holds. Judge Bradford granted a rule ordering the Wilmington City Electric Company to appear in court on October 12 and show cause why a temporary injunction should not be granted.

In the suit of the Electric Car Company of America and the Thomson-Houston Electric Company against the Walker Company, Judge Lacombe, in the United States Court, New York, last week, suspended the injunction previously granted and the defendants are permitted to use all apparatus now in actual possession and to sell all apparatus contracted for. The injunction is also suspended as to the manufacture of new apparatus. This suspension is to continue until one month after the opening of the next session of the United States Circuit Court of Appeals for the Second Circuit, in order to give the defendant an opportunity to secure a review of a previous decision.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Asbury Park, N. J.—Contracts for right-of-way are being made for a trolley road running from Atlantic Highlands to this city. The road will run from the Highlands to North Shrewsbury, thence to Navesink, Fairhaven, Little Silver, past Elkwood Park, Long Branch, West Long Branch, Interlaken to West Asbury Park. The excursion fare between Asbury Park and New York will be $1.

Beaumont, Tex.—A company of local capitalists have sent a petition to the city council asking for an electric street railway franchise. They agree to begin work within twelve months from the time the franchise is granted.

Bellows Falls, Vt.—A notice conforming to the law has been issued in relation to the application to be made this fall to the Legislature for a new charter for an electric railroad to run from Bellows Falls through Saxtons River to Grafton. The notice is signed by Ransom E. Smith of Saxtons River, who has been an active mover in the negotiations of the past six years for a road between here and Saxtons River.

Biddeford, Me.—As a result of a favorable report by experts who went over the route on a tour of investigation, work on the Saco River Electric Railway will be started before the end of the month. The contract for the construction of the road has been given to Boston contractors.

Chattanooga, Tenn.—President Divine has decided to equip the suburban lines of the Chattanooga Rapid Transit Company with electric cars.

Denver, Col.—The ordinance permitting the Denver City Railroad Company to change the motive power of its cable road to electricity, vetoed by the mayor, has been passed over the mayor's veto by the board of aldermen.—The owners of the cog road running up Pike's Peak have decided to change the motive power from steam to electricity. It is estimated that the cost of making the change will be about $50,000.

Leavenworth, Kan.—An ordinance has been introduced in the city council granting a franchise for the Leavenworth and Kansas City Electric Power & Mining Company. This is for the proposed electric road between Leavenworth and Kansas City that has been under consideration for some time. It is proposed to furnish electric power cheap to Kansas City factories, and also to haul coal over the road at night. A route to Kansas City was surveyed and the right of way secured last spring.

Lewiston, Me.—The Lewiston, Bath & Brunswick Electric Railway, which has just been completed, has been inspected by the railroad commissioners and pronounced by them the best system in Maine. In speaking of the success of the road, I. C. Libby, of Augusta, the chief promoter of the railway, said that the earnings of the road at the present time are between $1,000 and $1,500 a day, and that the promoters are well pleased with what they consider to be the finest electric railroad system in New England with the exception of the West End Company of Boston.

Millbury, Mass.—Work is in progress upon the construction of the electric road from Grafton to Worcester. The line will pass through North Grafton and Millbury Junction and connect with the Consolidated road's tracks in Worcester. The plan is to have the cars running by November 1.

Montreal.—On January 1 last there were 35 electric railways in operation in Canada, with a total mileage of 583. The number of passengers carried in the year was 83,800,000, as comparing with 16,170,000 by the steam railways on their mileage of 13,000. The paid-up capital of the electric railways in Canada is $18,700,000.

Pittsburg, Pa.—The Consolidated Traction Company is building an immense storage plant on Penn avenue for husbanding surplus electrical power for the various street car lines of the company. The building will be 8 stories high, with 25 feet front and 156 feet depth, giving a floor space of 3,750 feet. The entire building will be used in storing the power in great drums. It is thought the structure will be ready by the 1st of January.

Spartanburg, S. C.—The parties who recently purchased at public auction the property and franchises of the Etna Light & Power Company—A. H. Lezuky, W. E. Lown, G. S. Dunn and E. Norton—propose to take hold of the electric railway to Glendale and Clifton and complete it. The track is already graded beyond Glendale, but nothing has been done to it for two years.

St. Joseph, Mich.—The case of the dissatisfied stockholders who asked for the appointment of a receiver for the St. Joseph & Benton Harbor Street Railway Company has been stricken from the court calendar at

the request of the complaining stockholders, who disposed of their stock to unknown parties.

St. Louis.—The St. Louis, Fenton & Southwestern Railroad Company will erect an electric power plant. Electricity will be generated by water power.

Toledo, O.—The Bonner rail wagon was pronounced a success by all who witnessed a test of it made on the Perrysburg Electric Railway on the 9th inst. The wagon can be loaded in a farmer's barnyard, hauled by horses to the electric railway, placed on a specially constructed car and hauled to the city.

Wichita, Kan.—Petitions for an election to vote on the proposition of municipal ownership of street railway and electrical light plants have been signed here by the requisite number of voters, and Mayor Ross will issue a proclamation for a special election to decide whether bonds shall be issued by the city.

Worcester, Mass.—By the opening of the new electric line between Fayville and South Framingham, Worcester and Boston are connected by trolley, and it is possible to take a Marlboro car and by several changes get into Boston five hours later. The trip costs 60 cents.

LIGHTING.

Atlanta, Ga.—The sub-committee of the executive committee, consisting of one member of the executive committee from each ward, has passed a resolution providing that the question of owning a lighting plant by the city shall be submitted to the people at the city primary on October 5.

Creede, Col.—An incendiary fire destroyed the Amethyst electric power and light plant on the 7th inst. Loss $14,000.

Detroit, Mich.—The public lighting commission has reconsidered its action in ordering advertisements for new bids for 100 arc lamps and globes and awarded the contract to the Adams-Bagnall Electric Company, whose bid of $17.25 per lamp was the lowest. "The commissioners concluded," says the "News," "that they couldn't afford to allow an unsuccessful bidder to come in after bids were opened and, under pretext of making a lower price, secure a readvertisement of the contract."

Fort Wayne, Ind.—The council, by a vote of 15 ayes to 5 noes, has awarded the contract for electric lighting to the Jenney Electric Light Company. The contract is for five years and the rate per lamp $100.

Houma, La.—The council has granted Wilson & Jastremski, proprietors of the Houma Ice Factory, a franchise for fifteen years to operate an electric light and power plant, and they will proceed to erect the plant at once.

Delaware, O.—After a spirited discussion, in which the comparative merits of electric and Welsbach lighting were fully considered, the council decided to award the contract to the electric light company for ten years at $77 a year for each arc light.

McKinney, Tex.—L. A. Scott of Melissa has bought the electric light plant here owned by Henry & Pardeau.

Mt. Pleasant, Mich.—An election is to be held on the 21st inst. to vote on the proposition to issue $20,000 bonds for waterworks and $7,500 for an electric light plant.

Mystic, Conn.—An electric lighting plant is to be established here at once by Thomas C. Perkins of Hartford and associates. Efforts are being made to secure a franchise at Stonington, and if this can be obtained lights for both places will be supplied from the Mystic plant.

New Richmond, O.—At the election held on the 12th inst., the proposition to put in waterworks and an electric lighting plant was carried in the affirmative, 361 to 56.

Pittsburg, Pa.—The superintendent of the Allegheny County Light Company estimates that 250,000 electric lights, including arc lights, will be used for decorations in Pittsburg and Allegheny during the Knights Templars' conclave in October. When the cost of coal, wiring, labor and lamps are considered, the Pittsburg electrical display will eclipse anything attempted before, reaching $250,000 in expenditures.

Quincy, Ill.—The syndicate which owns the Thomson-Houston electric light plant, the street car line and the gas company, has also purchased the Empire Light Company's plant. The Empire Company was capitalized at $100,000.

Salem, Ill.—The city having decided to put in a $9,000 electric light plant, has awarded the contract to T. C. Reed & Co. of Chicago. The plant is to have a lighting capacity for fifty arc lights of 2,000 candle-power, and for commercial lighting 1,500 incandescent lights of sixteen candle-power. The plant is to be owned and operated by the city.

Seabright, N. J.—The power house of the Seabright Electric Light Company at Galilee was totally destroyed by fire on the night of the 14th inst. The loss was about $12,000.

Shelbina, Mo.—At the special election on the 6th, the proposition to issue bonds to the amount of $5,000 for the purpose of increasing the power of the electric light plant was carried by a large majority.

Tipton, Ind.—The Tipton electric light plant has been sold to J. S. Tarkington of Kokomo.

Vancouver, B. C.—In the disastrous fire at New Westminster on the 11th inst., the pole-line equipment, transformers, etc., of the electric light plant, valued at $30,000, were completely destroyed; the power house escaped. A large part of the town was laid in ashes.

Wahoo, Neb.—The local electric light plant was destroyed by fire on the 10th inst., and the loss amounts to several thousand dollars. The plant was owned by S. H. Jones of this city.

Winona, Miss.—The Winona Ice, Electric Light & Water Company has been organized by E. R. Blackston, D. B. Turner, C. S. Harris, William H. Witty and others, one of the purposes being to erect an electric light plant. The capital stock is $100,000.

MANUFACTURING, ETC.

Charlotte, N. C.—The Southern Electrical Company has been incorporated by S. B. Alexander, Jr., and others, who have purchased the electrical department of the Charlotte Machine Company and will operate it independently. Capital stock, $10,000.

Cincinnati, O.—The strike of the machinists of the Bullock Electric Company, which had been going on for several months, has ended in a compromise. Most of the strikers will be re-employed, and will work under the premium system, the introduction of which was the cause of the strike. The plant of the company will be removed to Norwood early in October.

Columbus, Ga.—The stockholders of the Columbus Power Company on the 9th inst. paid in $20,000 under a call for this amount, and the money was deposited in the Third National Bank. The "Enquirer-Sun" says the full amount of stock has been subscribed and payment of same will be called as money is needed to carry on the work of building the plant. All contracts for the building of the plant have now been signed and the work will be carried on as rapidly as money and men can do it.

Philadelphia.—A report to the Philadelphia Commercial Museum from Colombia, South America, states that there is a demand there for electric light fixtures for houses, offices, churches and stores.

Pittsburg, Pa.—The Pennsylvania Tube Works Company is making arrangements for the installation of a complete electric plant at their works in this city for the operation of the entire plant by electricity. The company proposes to expend about $100,000 on the erection of a central power plant of about 1,000 horse power. The electricity will be distributed through the lap and butt weld departments to perhaps 25 motors of 40 HP. each that will be placed near the various machines used in the manufacture of tubes and other productions of the works. The company is now using over 150,000 bushels of coal a month, and it is believed that with electricity it will be possible to secure the same amount of power with 100,000 bushels a month. Other iron and steel manufacturers are looking forward to the results of the change with considerable interest.

Washington, D. C.—The "Star" states that several applications have been received by the Government, through the War Department, for concessions of various kinds in Porto Rico, American capitalists being anxious to invest their money in the construction of steam and electric railroads and gas and electric light plants on the island. Adjutant General Corbin, by direction of the President, has informed one syndicate that sought a concession for the construction of a steam railroad from Ponce to San Juan, that no such proposition can be entertained at this time. The condition of affairs in Porto Rico, the syndicate was informed, is not such as to admit of this Government entering into any arrangement for such a concession as it asked; and until a determination had been reached by the properly constituted authority for the government of the island, no proposition for franchises or special rights in the island can be entertained. It is likely that Congress, in providing a scheme of government for Porto Rico, will provide also for the granting of franchises and rights of way in a manner similar to that now pursued in regard to such concessions in the various Territories of the United States.

MINES, ETC.

Pittsburgh, Kan.—The Western Coal & Mining Company has begun work on the construction of a 125 horse-power electric plant to operate machines at its coal mine, and Superintendent Craig thinks that inside of eighteen months fully 75 per cent. of the mining in this district will be done by machinery.

TRANSMISSION PLANTS.

Kalamazoo, Mich.—The Kalamazoo Valley Electric Company, organized by W. A. Foote, J. B. Foote and C. H. Frisbie of Jackson, R. H. C. Hoagland of Kalamazoo, and S. S. Hurlburt of Battle Creek, has been incorporated with a capital stock of $100,000. The purpose of the company is to develop the water power of the Kalamazoo river at Allegan, and distribute electricity to Allegan, Otsego, Plainwell, Kalamazoo and Battle Creek for power and light.

Tacoma, Wash.—The "News" states that a plan for a water power to be owned by the city has been submitted by C. B. Talbot. The initial scheme is for a power plant chiefly, to be erected on the Cheneius river at the Puyallup canyon, a distance of about 25 miles from Tacoma. Mr. Talbot says a ditch 8 feet deep can be dug to Maplewood Springs, near Puyallup, where he proposes to put in electric machines and run the current into the city for lighting and power. The fall would be 630 feet in the 20 miles, and a horse power of 5,000 to 10,000 could be developed, according to the width of the ditch. This work, Mr. Talbot says, can be done for $100,000, most of it for labor, and the plant once installed, he says, the city should derive a yearly revenue of $100,000 from it, enough to more than pay all municipal expenses and save the levy of any tax whatever.

COMPANY MATTERS.

Petersburg, Va.—In the suit of the Upper Appomattox Company against the Petersburg Electric Railway Company, the Hustings Court has entered an order for the sale of the road on November 10, to obtain money to pay off the liens which have been secured against the company and the bonds, amounting to $50,000, which were secured by deed of trust upon the property.

Syracuse, N. Y.—According to the figures submitted by Assignee Stolz, the creditors of the Electrical Engineering & Supply Company of this city will get about 25 cents on the dollar.

PERSONAL AND MISCELLANEA.

H. T. Eddy of the General Electric works at Schenectady has been appointed instructor in electrical engineering at Union College, to take the place formerly filled by Dr. Brackett.

The Pittsburg "Times" says: "Electricity will probably be used for the first time in the operation of a river dam in the new affair on the Ohio river at Merriman now under construction. The Government engineers have figured for some time on the adoption of this power instead of steam, and it is understood that an electrical plant will be installed as soon as the dam is completed. It has been estimated that a great saving can be made in the operation of the dam by electricity, and it is estimated that the work can be done quicker and with less labor. The motor arrangement at the lock gates will be simple and involve only a question of push and pull. The apparatus on the wickets will be a novel affair. A small motor will be arranged on a traveling crane, and this will travel back and forth and quickly lower or raise the wickets. This is now a slow and laborious process that is often attended with danger."

An ingenious form of speed-recording apparatus has been recently devised for use in some German railway experiments. While simple in design, it proved exceedingly effective, and showed, moreover, not only the speed at any particular moment, but the time in which stops were made, speed round curves, up grades etc. Electrical connections were made on the axle of the carriage in such a manner that a dash and a space were marked off at each revolution on a paper strip moved by clockwork. By marking the length of the ribbon corresponding to one minute of time and counting the number of dashes contained therein, the number of revolutions is given at once, and from the diameter of the wheels the speed can readily be computed.

RECENT COMPANY ELECTIONS.

Concord Street Railway Company, Concord, N. H.—Directors: John H. Albin, George A. Cummings, Howard A. Dodge, Paul R. Holden, George W. Abbott, Gardner B. Emmons, Hiram A. Tuttle.

Cortland & Homer Traction Company, Cortland, N. Y.—President, P. S. Page of Scranton; vice-president, Herman Bergholz of Ithaca; secretary and treasurer, G. Harry Garrison of Cortland.

Derby Street Railway Company, Derby, Conn.—President, H. Holton Wood, vice-president and treasurer, Chas. F. Clark; secretary, F. W. Wallace; assistant treasurer, B. W. Porter.

Nyack Traction Company, Nyack, N. Y. (new organization).—President, H. O. Howard, Chester, Pa.; treasurer, E. F. Walker, Philadelphia; secretary, G. D. Howell, Chester, Pa.

COMMERCIAL PARAGRAPHS.

We would call our readers' attention to the direct-reading Voltmeters and Ammeters manufactured by the Cherry Electric Works, 25 and 27 Third avenue, New York City. This well-known concern has made a specialty of low-priced electrical measuring instruments which may be advantageously used where high-priced instruments would be out of the question. These instruments, which are by no means toys, can be depended on for practical work, each being individually calibrated and guaranteed to be commercially accurate and, with proper care, to give good and accurate results. The price of these instruments is but $1.50 each, although the Cherry Electric Works are prepared to furnish a somewhat better grade of measuring instruments for five, ten and fifteen dollars. Ammeters and voltmeters of the above description would seem admirably adapted for experimental work where a high-priced instrument could ill be afforded.

The recent fluctuations in the prices of sockets, receptacles, cut-outs, insulators, etc., have made it somewhat difficult for the ordinary buyer to keep track of the market prices on these goods. The Electric Appliance Company, Chicago, have just issued a special price list of all of this material, giving trade prices that are strictly up to date. It is in the form of a small circular, which should be of

considerable value to the purchaser of staple electrical supplies.

Prosecution of Ticket-Scalpers.

Cincinnati, Sept. 7.—The people of Cincinnati have thrown a firebrand into the camp of the railroad ticket-scalpers. A short time ago the common council of Cincinnati passed an ordinance regulating the ticket-scalpers within the city limits. It provided that each scalper should be licensed and give bonds against the selling of spurious, counterfeit or stolen tickets. This morning eight ticket scalpers were fined in the police court and there are six others in jail. Judge Harmon, Attorney-General of the United States in President Cleveland's Cabinet, and other prominent lawyers appeared in the police court against the scalpers and secured their conviction. The interest taken in prosecuting those engaged in this illegitimate business is remarkable, but the people of Cincinnati have apparently determined to root out the evil from their city.—*From New York Tribune, Sept. 8, 1898.*

We are in receipt of a handsomely gotten up catalogue containing 186 pages and issued by the Western Telephone Construction Company, 250-254 South Clinton street, Chicago. It is profusely and handsomely illustrated, showing switchboards, telephone transmitters and receivers and views of the various departments of this company. Several of the closing pages are devoted to testimonials in the form of letters received from numerous independent telephone companies throughout the country which simply go to prove, what has already been known for some time, that this concern turns out a high grade and excellent quality of apparatus.

The Crane Company of Chicago has just issued a complete pocket catalogue of 428 pages showing its entire line. The catalogue contains dimension tables of screwed and flanged fittings and valves, and also a number of pages of useful information to mechanical engineers. We are authorized to state that a copy will be sent to anyone upon request.

INCORPORATIONS.

The Ironclad Resistance Company, Westfield, N. J.—to carry on an electrical business for the purpose of supplying light, heat and motive power. Capital stock, $25,000. Incorporators: Arthur W. Berresford, August P. Manning and Horace M. Williams.

The Storage Battery Supply Company, New York. Capital stock, $12,000. Incorporators: T. D. Bunce, F. E. Foster and W. E. Foster.

The F. L. Merrill Company, Portland, Me.—to deal in hardware and electrical supplies. Capital stock, $100,000. Incorporators: George O. Owen and Fritz H. Jordan, Portland.

The Mill Point Power Company, Amsterdam, N. Y.—to furnish light, heat and power to the city of Amsterdam and the towns of Charlestown, Florida, Amsterdam, Glen and Mohawk, and the villages of Fonda and Fultonville, and the towns of Johnstown, Perth, Mayfield and Broadalbin. Capital stock, $80,000. Directors: John Marsh of San Francisco, John Begley of Gloversville, H. J. Brady of Cooperstown, P. T. Brady and R. E. Drake of Syracuse.

The Kansas City Interurban Railway Company, Kansas City, Mo.—to maintain an electric railway in Kansas City. The company has purchased the Waldo Park dummy line and will convert it into an electric road, extending it so as to connect with the Mellier place line. Capital stock, $300,000. Incorporators: Henry Pfeiffer of Westport; H. G. Park, B. H. Chapman, C. H. Mathews and C. H. Chapin of Kansas City.

The Chicago Suburban Water & Light Company, Chicago, Ill.—to deal in water, gas and electricity. Incorporators: Charles F. Vogel, J. M. Gibson and Charles B. Wood.

The Hevner Road Bed Company, Camden, N. J.—to equip trolley and other railroads. Capital stock, $250,000, of which $20,000 has been paid in.

ELECTRICAL PATENT RECORD.

Letters Patent Issued September 13, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

610,620. Commutator-Brush Holder. William K. Bassford, Jr., Bound Brook, N. J. Filed Feb. 1, 1898.

610,705. Brush for Electrical Machines. Joseph W. Dickey, New York City, assignor of one-half to Charles E. Chapin, same place and Milford, Conn. Filed Dec. 8, 1894.

610,712. Apparatus for Starting and Controlling Electric Motors. Theodore W. Kloman, New York City. Filed April 4, 1898.

TELEPHONE AND TELEGRAPH APPARATUS.

610,701. Telephone System. William W. Dean, St. Louis, Mo., assignor to the Bell Telephone Company of Missouri, same place. Filed Sept. 3, 1897.

MISCELLANEOUS.

610,524. Electrically-Controlled Valve for Hydraulic Presses. William B. Cleveland, Cleveland, O. Filed Jan. 21, 1898.

610,539. Electric Clock. Frank Hope-Jones and George B. Bowell, London, England. Filed Dec. 18, 1897.

610,726. Art of Bending Armored Conduit-Tubes. William T. Ruete, New York City, assignor to the Interior Conduit & Insulation Company, same place. Filed Nov. 24, 1897.

610,767. Magnetic Separator. Ambrose Monell, Munhall, Pa. Filed Jan. 10, 1898.

TELEPHONE AND TELEGRAPH.

The Western Electric Company of Chicago has filed suit in the United States Circuit Court at St. Louis for an injunction against the Kinloch Telephone Company and Samuel M. Kennard, president of the company, enjoining them from using and making a certain multiple switchboard for telephone exchanges. The plaintiffs state that Leroy B. Firman, patentee, sold them the exclusive right to the invention January 7, 1881, and that they have been manufacturing the switchboards. H. J. Hanford, manager of the Kinloch Telephone Company, when questioned about the case, said that the suit was identical with the suit of the Western Company, which is controlled by the Bell Telephone Company, and was identical with the suit recently decided at Chicago by Judge Showalter in favor of the Kellogg Company, under whose patents the Kinloch is to operate. "I believe the application was filed for a bluff," said Mr. Hanford. "They only want to harass us in our work. Why, the court doesn't meet here till November and they file the application in September, just as the Kinloch is getting ready to open for business. The case is filed, too, in a court of no higher jurisdiction than Judge Showalter's. However, the Kinloch will go right on finishing up its circuits and getting in shape to open up. We have now more telephones in this city than the Bell, and orders are coming in daily."

French advices state that experiments are being conducted on the Paris-Bordeaux line with a telegraph invention of M. Mercadier, which he has been working on for many years, and which, it is claimed, enables the working of twelve Morse transmitters simultaneously on the same line. This result is brought about by the use of alternating or interrupted currents. Each transmitter receives its current through a tuning fork, having a special note, its vibrations being electrically maintained. These vibrations furnish a current of the proper period to cause the resonance at each application in the proper receiving circuit, which has its self-induction and capacity adjusted for this result. This receiver is a telephone (a monotelephone, as it is called by M. Mercadier), so constructed and arranged that the acoustic resonance qualities also help to damp out from the signals received everything not intended for it. These signals are read in the ordinary way, by ear, aided by rubber tubes, like those used on phonographs. The sifting out of the signals, it seems, is very perfect, each receiver giving no evidence of those signals not intended for it, except a slight murmuring, very indefinite and not at all bothersome. The instruments are called duodecaplex.

Telephone and telegraph companies in Michigan pay taxes to the State on the basis of their valuation instead of in the form of specific taxes, as in the case of railroads, express companies, etc. The law provides that such companies shall pay taxes at the same rate that other property in the State is assessed. For this year the telegraph companies were assessed $18,499.93, of which sum the Western Union Telegraph Company paid $15,711.40. The telephone companies paid $41,086.78 in taxes, the appraised valuation being $1,369,560. The Michigan Bell Telephone Company paid $26,348.32, the Detroit Company $6,460.02, the Citizens' Company of Grand Rapids, $2,586.83, and the American Telephone & Telegraph Company $1,630.37. There are now thirty-one telephone companies in the State where there was but one ten years ago.

The Worcester, Mass., *Post* says there is another telephone company proposed as a rival of the New England Telephone & Telegraph Company in that city. It is projected by F. Plummer of Plummer, Ham & Richardson, and has no connection whatever with the People's Telephone Company, which I. L. Currier and Alderman James H. Mellen are talking of organizing. Mr. Plummer says that a meeting will be called in the interests of his company shortly and if business men subscribe for stock it will be incorporated.

The Commercial Cable Company, it is reported, has perfected arrangements to lay a direct cable from New York to Ponta Delgarda, on St. Michaels, the most eastern island of the Azores group, which is connected already with the other islands by submarine cable. At present there is no direct telegraphic communication with the Azores from the United States, messages being forwarded by way of London, and the cable facilities are so poor between that city and the islands that there is much delay in the transmission of messages.

The Mississippi Valley Telephone Company has made an arrangement with the Dakota Central Telephone Company by which the former company, now being located in St. Paul and Minneapolis, will have connection with 1,000 miles of wire, a portion of which reaches Nebraska towns.

The city of Richmond, Va., intends to continue its fight with the Southern Bell Company, which, in the language of the Richmond *Times*, "is now doing business in Richmond by grace of an injunction granted by Judge Nathan Goff, of the United States Circuit Court." The Board of Aldermen on the 13th inst. suspended its rules and adopted unanimously a resolution providing for the employment of assistant counsel to the city attorney in the conduct of the case, which is now pending in the Supreme Court of the United States.

The city council of Helena, Ark., has passed an ordinance regulating the rates to be charged for telephones in that city. The rates fixed in the ordinance are $1.50 for residences and $2 for business houses. The present rates are $3 and $4 respectively. The Southwestern Telephone & Telegraph Company, through its attorneys, fought the reduction bitterly and say they are going into the courts and will test the right of the city to regulate its rates.

The movement for independent telephone toll lines in northern Indiana is taking shape and contracts have already been let for several hundred miles of toll lines. With the building of first class independent toll lines, the independent local exchanges, which have been at a disadvantage because they lacked outside connections, will grow much more rapidly, and in cities where there are no independent exchanges, new companies will spring into existence.

Among the passengers on the steamship Empress of India, which sailed from Vancouver last week for Hong Kong and Yokohama, was James F. Scrymser, president of the Pacific Cable Company of New York, who is going to Japan to try to obtain a subsidy for the cable company. He says capital has been guaranteed for the cable from San Francisco to Australia.

English capitalists have secured a controlling interest in the New Westminster, B. C., and Burrard Inlet Telephone Company. The ramifications of this company extend over a vast area. The transaction is important, not only because of the individual sale itself, but as showing that British capitalists are again turning their attention to Vancouver and surrounding districts as a field for profitable investment of money.

The Bell Telephone Company has purchased the Greenville, Texas, Independent Telephone Exchange. The exchange was built by Mr. Hawley and equipped with Western Telephone Construction Company's apparatus. It worked so successfully that the monopoly was forced to buy it or abandon that field.

C. T. McCreary, the superintendent of the new People's Telephone Company at New Orleans, has assumed charge of the work of putting up the telephones in that city. All the wires in the business portion of the city will be laid underground.

The Citizens' Telephone Company of Magnolia, Miss. has been granted a franchise to maintain a local and long distance telephone system in Magnolia. The company has been incorporated.

A franchise to establish a telephone exchange in Washington, Ga., has been granted to the firm of Neal & Grier of that city. They agree to connect their system with the Elberton telephone exchange at Elberton.

A telephone line will be constructed at once from Elizabeth via the Little Kanawha Railroad to Parkersburg W. Va.

The local telephone exchange at Cuero, Tex., has been sold to the Southwestern Telephone Company.

Under the new tariff of Japan, the duty on telephones and parts thereof is 10 per cent. advalorem.

New Companies Incorporated.

The Havana Telephone Company, Havana, Ill. Capital stock, $5,000.

The Bryan Telephone Company, Bryan, O.—to build and operate a telephone line between Bryan and Waseon. Capital stock, $20,000.

The Cuyahoga Telephone Company, Cleveland, O.—to construct telephone lines in Ohio and operate them as competitors of the Bell Company. Capital stock, $3,000,000. Incorporators: J. B. Hanna, J. B. Hodge, H. Clark Ford, H. A. Everett, E. W. Moore and W. B. McGraw.

The North Park Telephone Company has been incorporated at Cheyenne, Wyo., its purpose being to operate telephone line between Walden, Col., and Laramie, Wyo Capital stock, $15,000. Incorporators: Monte Blevins, J. Mosman, G. F. Scott, O. E. Mosman, M. A. Ward.

The American Electric Telephone Company, Chicago, has certified to an increase of capital stock from $100,000 to $130,000.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12⅛c.; Lake, 12¼@12⅜c.; casting, 11⅞@12c.

The Edison Electric Illuminating Company of Brooklyn has declared its regular quarterly dividend of 1½ per cent., payable to stock of record September 30.

The Cincinnati & Hamilton Electric Railway Company has placed on file in the recorder's office at Cincinnati a mortgage for $500,000 in favor of the American Trust Company.

Secretary Ely of the New York Stock Exchange has issued a notice that the old stock of the General Electric Company will be traded in in the unlisted department and will be quoted on the tape as "G. E., old."

The Boston Elevated Railway Company has declared to the common stockholders of the West End Street Railway a semi-annual rental dividend of 3½ per cent., payable to stock of record September 17. Books will reopen October 2.

The earnings of the Montreal Street Railway for the eleven months ending September 1 amounted to $1,323,085, an increase over the corresponding period of last year of $110,289. August was a big month and the earnings amounted to $143,801.

The American Automobile Company, with a capital stock of $500,000, filed articles of incorporation in the county clerk's office, Elizabeth, N. J., on the 17th inst. The chief office of the company will be in Plainfield, N. J. It will engage in the manufacture of motors and other appliances.

A circular has been issued by the directors of the Royal Electric Company of Montreal calling a special meeting of the shareholders on October 18 for the purpose of authorizing an issue of preferred stock, and the acquisition of shares in the Chambly Manufacturing Company for an additional amount of $100,000.

The Western Union Telegraph Company's annual meeting will be held October 12. The regular quarterly dividend of 1¼ per cent. on the stock has been declared, payable October 15, books closing September 20 and reopening October 17. The estimated earnings for the quarter were $1,750,000; actual $1,677,202.

The first mortgage bondholders' committee of the Terre Haute (Ind.) Street Railway Company gives notice that, more than 87 per cent. of the bonds having been deposited, the limit of time for receiving further deposits is extended to October 1, after which date bonds will only be received subject to such penalty as the committee may impose.

The Cleveland "Press" says "there is a general feeling among local brokers that the controversy over the Big Consolidated is ended. There is no market for the stock. The leaders of the two factions say there is nothing more that can be done. Each side is positive it controls enough stock to carry the election in January, and all that can be done is to wait. While each side tells this story and claims it has a controlling interest in the company, it is not taking any chances. Although neither side is buying any stock, both are getting options wherever they can."

A dispatch in the N. Y. "Journal" dated, Chicago, September 19, contains the following: "The Leiters—Levi Z. and Joseph—made a new move to-day in the direction of their contemplated control of the Chicago street railway system. The Chicago City Railway Company, of which Levi Z. is one of the largest individual owners and Joseph one of the recently elected vice-presidents, has undoubtedly secured control of the 'Alley L' road, one of the effects of the deal being to send up the stock of the latter company almost four points on the local Stock Exchange."

An advertisement in the Wheeling, W. Va., "Intelligencer" announces that the annual meeting of the American Railway Electric Light Company will be held at the office of the company, No. 14 Stone street, New York, on the 4th of October at noon, at which an election will be held of directors and a resolution will be offered increasing the number of shares of stock of the company from 50,000 to 60,000 shares of the par value of $50 each, thus increasing the capital stock of the company from $2,500,000 to $3,000,000. Transfer books will close September 23 and reopen on October 5.

The amalgamation of the Walker Company of Cleveland with the Westinghouse Electric & Manufacturing Company, which was announced officially on the 17th inst., had been meditated for some time and was no great surprise to any one in the electrical business. The two companies have suffered greatly from litigation, and their misfortunes have probably tended to bring about the union which has been accomplished, their common antagonist, the General Electric, having apparently consented to, if it did not encourage the match. This concord of warring interests will be reflectively studied by all engaged in the electrical trade.

The Brooklyn "Eagle" treats as a fact the announcement that a large block of stock of the Nassau Railroad Company has been sold by R. T. Wilson to ex-Gov. R. P. Flower and other representatives of the Rapid Transit Company. It intimates that the opposition of the Johnsons, who are deeply interested in Nassau securities, to the lease is purely a matter of money and will be maintained unless they are paid par for their stock. In the case of P. H. Flynn, another heavy holder of Nassau stock, it says his opposition "is more personal and therefore on more lasting grounds, and there is every reason to believe that he will fight any plan leading to a Flower control of the road, which was authorized and constructed largely through his efforts and as a competitor and rival of the Transit Company's, without a fight that is likely to rival the Long Island Traction contest in bitterness and longevity."

T. L. Livermore and Edwin F. Atkins, the committee of preferred stockholders of the General Electric Company, have issued the following circular to depositors of preferred stock under agreement of June 1 with the American Loan & Trust Company: "Your committee have been in negotiation throughout the pendency of the litigation with the General Electric Company, but have been unable to adjust the controversy with the company to their satisfaction. They have now received from individuals a proposition which they have decided to recommend you to accept. It is that we sell our shares and rights in respect thereof at $100 a share cash, on or before October 1, 1898, with interest from July 1, 1898, at 6 per cent. This is not as favorable a result as we have hoped for. It amounts to five years' back dividends and $65 per share for the unreduced stock. In view, however, of the doubtful character of the questions raised, the protracted and expensive litigation involved and the comparatively small number of shareholders, say one-fourth of the preferred stock, taking part in it, we have accepted the offer for ourselves and recommend it to you. The price above named will be paid without any deduction for the expenses of the proceedings to date. Those who elect not to accept this offer either may acquiesce in the reduction of their shares pursuant to the recent action of the company and accept new stock certificates for the reduced amount of stock, or at their election take up and pursue the pending litigation at their own risk and expense. We have instructed the American Loan & Trust Company to dismiss the pending suit, unless, prior to October 1, 1898, some depositor shall take suitable action to continue the litigation as above stated. We have already given instructions to dismiss the suit forthwith as to all the complainants except the American Loan & Trust Company. The 10,000 shares of stock on deposit with the trust company were sold to the syndicate on a basis of $100 per share and interest from July 1 at the rate of 6 per cent. cash."

ELECTRICITY.

Vol. XV. NEW YORK, SEPTEMBER 28, 1898. No. 12.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The American Indies Company.

In a recent editorial we pointed out what excellent fields both Cuba and Porto Rico offered for electrical enterprises. Since then a company to be known as the American Indies Company has been organized for the purpose of developing the resources of these two islands. It is capitalized at $18,000,000 and incorporated under the laws of New Jersey. According to the prospectus recently given out, the new enterprise is to cover every important field, and should it prove successful will almost monopolize the electrical industry in those islands. Under its charter the company has the right to generate, accumulate, distribute and supply electricity for light, heat, power and signaling purposes; to construct, own and operate plants for the conveyance of electrical current for telegraph, telephone and various other purposes; to construct and operate telephone exchanges; to manufacture and supply gas for fuel and illuminating purposes, and to light cities and buildings. It has the right to acquire real estate of almost every description and to mine, smelt and refine. Its charter further empowers the company to own, build and operate sewers, water works and all other public and private improvements, as well as to own and operate steamships or other vessels. The secretary of the company, Mr. Henry D. Macdona, in a recent issue of the New York *Herald*, is credited with the following statement:

"The company has been in process of formation for several months and was organized for the purpose of taking advantage of the extraordinary economic transformation now at work in Cuba and Porto Rico. It intends to renovate old enterprises and create new ones in those prodigiously rich islands, and to that end has secured the co-operation of some of the most conservative men of wealth and enterprise, who, even under the late restrictive and oppressive régime, have gained distinction as merchants and administrators, and who, representing the new commercial aspirations of those communities, have enlisted both capital and experience in this undertaking.

"Under the new commercial conditions, industries, especially those concerns operating public franchises, will need readjustment, reorganization and development. This is the work the American Indies Company was organized to accomplish."

The incorporators are all said to be wealthy men, among them being Mr. Anthony N. Brady, well known to the electrical fraternity for his connection with the "Hucklebery Road," and as one of the directors of the Walker Manufacturing Company.

That there is an unlimited field for electrical undertakings in both Cuba and Porto Rico is not to be doubted, and it only remains to be seen what the American Indies Company will accomplish.

* * *

Electricity from the Sun?

The utilization of the sun's rays to obtain electricity is a problem on which scientists have been at work for a number of years. From time to time a sensational daily will announce in prominent type that a method has been devised to accomplish this, and that is usually the last heard of the alleged discovery. Some months ago Mr. Nikola Tesla was credited with having "harnessed the sun," and now we hear of another invention of similar nature by Prof. Elmer Gates of Washington. He claims to be able to draw electricity from the sun's rays by means of an ordinary battery cell, a magnet and a crystal. In an interview reported in the Philadelphia *Press* he is credited with the following statement:

"I took a cell just like one of these, and with the aid of a magnet and a crystal I secured enough electricity to operate a little motor. I brought it all about by simply reversing one of the currents, one of those two that are always moving in opposite directions. No, I am not reversing nature. It is simply taking advantage of one of nature's possibilities.

"Like every one interested in electricity, I have been deeply interested for many years in the solution of the problem of how to produce heat without fuel. The saving by such a discovery would, I realized, be enormous, and yet such a discovery to be of any practical value must be simple. Can you find anything more simple than a magnet and a crystal?

"I am not prepared to say yet just how I accomplished the result. I am not of a sordid disposition, but I am sufficiently worldly to understand the necessity of protecting inventions before making them fully public. But you can be assured that electricity can be drawn from sunshine just as you would draw cider from a barrel. The one process is as simple as the other."

That the heat emitted by the sun will eventually be made use of for power purposes is by no means improbable, but we question whether this will be accomplished in any such simple way as above stated.

It might be possible to concentrate the sun's rays in such a manner as to cause water to generate steam in a boiler, but in such an event some practical method of storing the heat obtained during the day for night use would have to be devised. In this connection it might be in place to mention a rather ingenious and unique scheme to indirectly make use

of the sun's rays for generating electricity on the Nile in Egypt. It is suggested that water be stored in sealed tanks with glass coverings similar to that of a conservatory. The heat from the sun expanding the air in the tank containing water, at the lowest level, it is thought, would force it into a tank at a higher elevation which would be kept cool by screening. This process would be repeated several times, the water each time passing to a tank at a higher level. It is then proposed to utilize the power of the fall for running turbines which would in turn operate dynamos. Whether such an arrangement could be made to work successfully is extremely questionable, but even such a scheme would seem more practicable than some of the suggestions constantly being advanced for the utilization of the sun's rays for generating electricity.

Determining Temperature Electrically by Sound.

An instrument has lately been placed upon the market by means of which the degree of temperature may be determined electrically by sound. This electrical auricular thermometer, as it might justly be termed, is the invention of Dr. George C. Whipple, biologist of the water-works in Brooklyn. It consists of a battery box to which is attached a long strand of insulated wire, the latter having at its extremity what at first sight appears to be a coil of ordinary bare wire, but which in reality is a hollow tube in which is imbedded two parallel wires, one of german-silver, the other of copper. An ordinary telephone receiver is connected to the other side of the box, while on the top of the latter is situated a dial marked with the degrees of temperature both above and below zero. A movable pointer is attached to the center of the dial. The modus operandi of the apparatus is simple. To determine the temperature of, for instance, a liquid, the bare tubing containing the german-silver and copper wires is immersed and the telephone receiver placed to the ear, when a buzzing sound will be heard. The pointer on the dial of the battery box is then moved around until the noise made by the diaphragm of the receiver ceases, when the degree of temperature of the liquid will be shown on the dial by the pointer.

The instrument is another exemplification of the Wheatstone bridge, the whole operation being simply one of balancing a resistance. At different temperatures the german-silver and copper wires do not offer the same resistance to the passage of the current, and of this fact Dr. Whipple has taken advantage and arranged a mechanical resistance in the dial box which may be made to balance the resistance of the bare wires, the telephone receiver being employed merely as a means of ascertaining when the resistances balance. An instrument of this description is said to have many advantages over the ordinary thermometer for special applications. For instance, an electrical sound thermometer can be installed in a large building in such a manner that the engineer located in the basement who has charge of the heating may, by placing the receiver to his ear and moving the pointer, ascertain the exact temperature of every room. The State House in Boston is thus equipped, and the arrangement there is said to have proved very satisfactory.

Another field open to the electrical thermometer would seem to be in cold storage warehouses. Heretofore when it was necessary to ascertain the temperature of any room in such a building it had to be opened, thus admitting a quantity of warm air, which was by no means desirable. With a view to doing away as much as possible with this opening of the rooms, the refrigerating plant was constantly kept operating under high pressure, which was by no means economical. Now each room in such a warehouse may be provided with an electrical thermometer, all the wires leading to a common switchboard. By connecting in circuit one room after another, placing the receiver to his ear and manipulating the pointer, a person would be able to determine the exact temperature of each apartment. But probably where a thermometer of this description would be most valuable would be in the workings of the United States Weather Bureau. One of the New York dailies referring to this invention recently, said:

"It is the purpose of Dr. Whipple to carry on a series of experiments with his thermometer attached to kites and balloons. It has been almost impossible with the apparatus which heretofore has been in use by the Weather Bureau to obtain a continuous record of the temperatures of the upper strata of the air. Yet upon this depends the efficiency of the Weather Bureau predictions. In fact, it is said that the meteorology of the future will depend mostly upon what is learned of the condition of the elements high above the earth. One of these instruments invented by Dr. Whipple could be sent up in a captive balloon or on a kite string and kept in operation for days. A very accurate curve representing the successive temperatures of the upper air might be obtained in this way. As the conditions which periodically affect the surface of the earth always exist up above for some time beforehand, some very accurate predictions might be made as to weather in store for us."

Under the Searchlight.

Notes and Comments on Various Topics.

IN the financial article of the *Sun* on Monday last, some of the recently effected combinations and some contemplated are referred to as follows:

In Brooklyn there has been talk of a sale to the largest owners of the Rapid Transit Company stock of enough of the stock of the Nassau Electric Railroad Company to give them the control of that concern also, while the amalgamation of the Edison Electric Illuminating Company of the same city with the Kings County Electric Light and Power Company, which has been pending a considerable time, is nearly consummated. An alliance of some sort between the Westinghouse Electric Company of Pittsburg and the Walker Company of Cleveland has also been announced. In addition, the committee of the minority of the preferred stockholders of the General Electric Company have formally given up their struggle against the majority, and submitted to be despoiled of 35 per cent. of the par of their holdings. Peace consequently reigns in the General Electric, as it did in Warsaw, after the Russian General had massacred half its inhabitants.

* * *

A CERTAIN remote town in Canada which, owing to its size, was unable to support a minister of the Gospel the year round, is said to have frequently been in straits during the prolonged absences of the holy man for some one to perform marriage ceremonies. A way out of the dilemma was thought to have been found by a keen-witted inhabitant in the phonograph. One of these was procured in which the nearest Justice of the Peace was induced to recite the marriage service, omitting names however. A number of impatient couples are said to have been married in this novel fashion, the names of the contracting parties being uttered at the proper moment by one of the witnesses. Marriage by phonograph was becoming quite popular and there was serious thought of permanently substituting Mr. Edison's invention for the services of a minister, when one of the cloth appeared in town and shocked the community by announcing that marriages consummated in this manner were no marriages at all in the eyes of the Lord. There was consequently a scramble to be remarried, the minister pocketing the fees.

* * *

THE following advice, although intended for English telephone service, might be occasionally found useful in this country:

To the Editor of the *Pall Mall Gazette*: Sir—It has been left to the Salvation Army to find another way out—this time of the telephone trouble. In their telephone boxes they place the following notice: "Ye have need of patience.—Heb. x. 8." May I suggest that the Secretary of the Telephone Company serve out to their clients a notice bearing a similar quotation? One might gaze at the text and breathe the sentiment as an excuse for saying prayers, and some of us may yet live to bless, and not to curse.—I am, Sir, yours truly, H. Greville Montgomery, Savage Club, August 26.

* * *

THE El Paso *Times* publishes the following interview, which is well worth producing if only to show that much-maligned Brooklyn has a formidable rival:

"Our Juarez street car lines," said Mr. Max Weber the other day, "are getting their concessions arranged for running electric cars, and we will be ready to put in an electric system as soon as the El Paso lines join us. I fear, however, that the people of El Paso and Juarez are not sufficiently advanced in street car civilization for electric lines. Why, electric street cars in El Paso would kill more people the first year than were killed in the war between the United States and Spain. In Juarez the street car mortality would not be so great because we have laws over here to keep the people off the tracks. But in El Paso the courts protect the people in sleeping on the street car track. Even with your present slow mule-box system it is necessary to employ a man to walk in front of the cars to persuade people camping on the track to get off and permit the cars to pass. In El Paso when a man gets too full of beer to fight he goes out to hunt a car track to lie down on and go to sleep, and if his slumbers are disturbed by a street car the courts make the car company pay the poor, over-worked, down-trodden sleeper big damages. Why, the El Paso street car companies have been sued fifty times for disturbing sleeping drunks, while our lines in Juarez have not had a single suit. In Mexico people are not allowed to go into camp on a street car track nor are children permitted to jump on and off cars in motion. I think it would be a good idea for El Paso to inaugurate a campaign of education; teach your people that a street car track is not a free lunch counter or a lodging house."

* * *

THE latest electric plaything is an electric cane lamp. The handle of the cane contains an incandescent lamp, the two poles of which are connected with the plates of a battery. Below this is a small chamber to carry the battery fluid. When it is desired to use the lamp the cap is taken off and the cane inclined, so that the liquid it contains comes in contact with the electrodes. A current is thus produced that will, it is asserted, keep the light going for an hour, which ought to be a sufficient allowance of time for the sometimes somewhat difficult search for the keyhole, provided that the lamp works.

* * *

Electricity for Tunnel Haulage.

THE passage through the St. Gothard tunnel is described to us, says the *Electrical Review*, London, by a recently returned traveler as having been something appalling during the recent hot season. With smoking locomotives burning briquette coal the journey of 9¼ miles, which occupies about 20 minutes, is almost unbearable. Our informant states that there is not far from the tunnel mouth a stream of fair size, which falls about 1,100 feet in a course of four miles by road, so that the water could easily be piped to Goeschenen, a distance of 2¾ miles by road from the Devil's Bridge, nearly 1,000 feet above Goeschenen, and utilized on Pelton wheels to work the tunnel by electricity.

* * *

THE *Electrical Engineer* of London aptly says: "What constitutes the claim to the title 'Electrician'? Whatever the answer may be, the self-styled or properly-styled electrician is having a rough time of it lately. The daily papers chronicle one shot at one place by roughs, another injured and sent to the hospital in another place, a third assaulted, and so on, till, as we say, the 'Electricians' seem to be having a bad time. Really there is little kudos in being styled an electrician when a wire-stretcher or a cable-layer is included in that category."

THE SINGLE VS. THE DOUBLE TRUCK CAR.

Mr. J. Hector Graham Takes Exception to Some of Mr. McCulloch's Views.

Editor ELECTRICITY.

DEAR SIR: I have read with interest the article by Richard McCulloch on the "Comparative Earnings and Economy of Operation Between Single and Double Truck Cars for City Use" that was read at the Convention of the American Street Railway Association, September 6 to 9, and printed in your issue of September 14, and I hope you will spare me space in your paper to show that Mr. McCulloch did not know what he was talking about, and that if he had acquainted himself more fully with the art that he professes in his paper to understand he would not have made statements that he has. There is one qualifying clause, however; he states: "In this paper the writer has not attempted to prove that either the single-truck or the double-truck car is the better type; he has merely attempted to discuss the subject to bring out the strong points and the weak points of each type." Well, he certainly brought out the weak points of the double-truck car. To quote more fully from his paper—he says: "Twenty-two feet may be arbitrarily established as the limiting length of the body of a single-truck car, and if we wish to use car bodies longer than this, we must adopt some truck which will avoid oscillation." I wonder how Mr. McCulloch can make such a statement as this in view of the fact that there are nine-bench open cars and twelve-bench open cars in successful operation on four wheels, and that they are from 30 to 34 feet in length.

In this city the standard open car is nine-bench, seating 45 passengers, and it is being carried on four wheels. Now to make a comparison that will show the development of the art, we will take a 60,000 lbs. capacity freight car with tare 40,000 lbs.; here we have 100,000 lbs., carried on eight 550 lb. wheels, each wheel carrying a load of 12,000 lbs. The weight carried per lb. of wheel is $22\frac{8}{11}$ lbs. The speed of this car varies from 20 to 40 miles an hour, and it is found to be a safe vehicle to operate.

Let us turn now to some of Mr. M.'s figures in reference to double-truck cars. If we take as a standard a 26 ft. car carrying 36 passengers, we find the weight of this car to be practically 24,000 lbs. He has not stated whether his wheel weighs 300 or 350 lbs., but I will take the wheel at 350 lbs. and we find that it carries a load of 3,000 lbs., and the weight carried per lb. of wheel is 9 lbs. Comparing this with a 20 ft. car weighing 16,000 lbs. carrying 28 passengers, considering the weight of wheel 300 lbs., we have a load per wheel of 4,000 lbs. and the weight carried per lb. of wheel is $13\frac{1}{3}$ lbs., showing that as between the weight carried per lb. of wheel in the two cars there is over 50 per cent. in favor of the short car, and as to the passengers carried, we find that the 26 ft. double-truck car carries 36 passengers; now as we desire to prove that Mr. M.'s figures are all wrong as regards the short car on four wheels, we have decided to take a nine-bench open car which carries 45 passengers and refer him to any number of twelve-bench open cars that seat 60 passengers, and frequently, on special occasions where traffic is heavy, these twelve-bench open cars on 4 wheels have been known to carry 125 passengers. We have the letters in our office from railway companies operating our 4-wheel trucks stating this to be a fact, and the round trip of 10 miles has been made inside of an hour. Mr. M. says: "Before the advent of the electric car, the horse car had become such an established institution in this country that certain standards as to track and rolling stock had become fixed." Certainly they had. For sixty years the leading car-builders of the country had been exercising all their skill and energy to build cars as light and strong as it was possible to do it, not for the reason that the horses could not pull the load, but because the railroad officials then desired to buy the very best in the market, as they did not want to pound their tracks out in five years or have their rolling stock racked to pieces inside of twenty years. The railroad officials then displayed not only considerable business acumen but also a great deal of mechanical skill, and to-day there are horse cars in this city running on 4-wheel electric trucks that are in a better condition after 10 to 15 years of service than some of the brand new 25-foot cars that have not been in service a year.

Mr. M. further states: "When a mechanical motive power replaced the horses this limit disappeared and almost the first improvement made in the rolling stock was to increase the size of the bodies." Now, as we stated in the beginning of our letter, if Mr. M. was familiar with the art he would have explained such statements as these. If the old horse-car body was strong enough to carry the load it was built for, and the weight of the car was made proportional to the weight of the passengers carried, why was this principle not carried out when electricity was adopted? For if there is a limit to the load the horse could pull, there must be a limit to the load the motor can pull; in the case of the horse it was corn, in the case of the motor it is coal, and both of these cost money. If it was good business policy to reduce the weight of the horse-car so that the horse would not be overloaded, would it not be a similarly good policy to reduce the weight the motor has to pull? Surely if it was unprofitable in one case it is unprofitable in the other, and to-day in the United States there is no department of the liberal arts or of manufacture that has been so hopelessly overburdened with the products of men who did not know and who do not now know the requirements that the art demands as electric railroading. Have the passengers increased any in weight to require an equipment three or four times as heavy as the equipment was when the horse was the motive power? These are questions that practical men like Mr. M. should explain before they begin to make comparisons between the conditions that are radically wrong to start with. Now Mr. M. goes on to state: "It is evident that since a car equipped with double trucks has eight wheels and one equipped with single trucks has four, the former will be more expensive to supply with wheels." That is so self-evident that it requires no demonstration even to the unwashed. Again he states: "It will be seen by reference to Table 1 that the greater part of the increased expense of maintaining the double truck is due to the renewals of wheels and brake-shoes." And again: "An examination of the tables will reveal the fact that the power required for the propulsion of the car, and the care and repairs which the motors demand, are much greater in the case of the double-truck car;" and that "the wear of the rails of a street railway track is due to the grinding action of the wheel on the rail, and this is proportional to the weight on the wheel, but is intensified by the dirt on the rail which causes the wheel to slip and act as an abrasive agent after the slipping has begun. The weak points of a street railway track, however, consist of the joints and the opening in the special work. The energy of the blow which the wheel strikes as it passes a low joint or a crossing is equal to the product of the weight of the wheel and the height of the drop." Therefore, we may add for Mr. M.'s benefit that there is to be added to the energy of the blow the load the wheel is carrying; when the load finds its support has dropped from under it, the load follows, and as the wheel sets itself in the low joint the car body comes down with it and the springs, which are usually placed on the axle-box, are compressed and the weight acts similarly to the spring handle of a sledge-hammer, adding greatly to the energy of the blow. Mr. M. continues: "Therefore on any given track both the wearing action of the wheel and the destructive action of the wheel are proportional to the weight which rests upon it." (To this we take decided exception, as we have stated above.) "If the number of wheels under a car be increased, the number of wheel blows which a low joint receives is also increased, but the intensity of each blow is diminished." If Mr. M. infers that the energy of the blow is decreased, he has not stated the case fairly, for this reason: in double truck the two wheels have a short, rigid wheel-base, when the forward wheel strikes the low joint it throws the blow back to the rear wheel and the rear wheel when it meets the low joint throws the shock forward, doubling the shocks instead of diminishing them, and it is not the energy of the blow that is destructive to the low joint so much as it is the number of blows—for instance, you go into a large forging mill and you will find that they have hammers that are quick in action and they repeat the blows as quickly as possible to accomplish the best results, and this is exactly what results from the double-truck car. Continuing Mr. M. says: "Double-truck cars are at no disadvantage as compared with single trucks in this respect, unless the weight of the car be increased." Well, if increasing the number of wheels and axles 100 per cent., together with the same increase in axle boxes, springs, journal bearings, truck frames, oil and waste and additional care, is no disadvantage, we respectfully inquire if it is an improvement. Sincerely, J. HECTOR GRAHAM.

Boston, Sept. 21, 1898.

COST OF ELECTRIC POWER FOR STREET RAILWAYS AT THE SWITCHBOARD, STEAM AND WATER POWER.*

BY R. W. CONANT.

(*Concluded from page 167.*)

[The tables and diagrams referred to in the following will be found in connection with the first part of Mr. Conant's paper in our last week's issue, reference being made to them throughout the whole article.—ED.]

I shall next call to your attention station No. 3, whose equipment differs from the standard as follows: It has two units instead of three. Each generator is 800 KW., making a capacity of about half that of the standard. The generators and engines are direct connected, the latter being compound condensing, smaller of course than the standard, but in other respects similar. Three 500-HP. water-tube boilers, economizers and heaters complete the important part of its equipment.

Group No. 3 indicates the cost of power for this station. At the extreme left is standard, the next column showing costs per KW. hour, averaged for one year. At the extreme right of the group is the average for a light month, and at the left of this is the month of high output. It is to be noticed that the total cost of operation for the year is somewhat greater than standard, coal expense practically the same, labor and general expense somewhat higher. Coal expense being the same does not in this instance indicate that the economy of the station is as good, as by referring to the table it will be seen that the pounds of coal per KW. hour are 2.61, as against 2.2 for standard. This increase is, however, nearly balanced by the reduction in the price per ton, which was $2 60, as against $3 for standard. It might be expected that on account of the diminished size of the station the labor expense would be larger on account of requiring more men per 1,000 KW. An examination of the table shows, in fact, that the men per 1,000 KW. is nearly double what is required for standard. This would double the labor expense, providing the rate of pay and load factor remained the same, but by a coincidence the rate of pay is

* Paper read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

lower and the load factor enough higher to bring the labor expense to nearly standard figures.

To illustrate the effect of a high load factor in reducing the cost of labor per KW. hour it will be interesting to look at the next shaded column for this station, which represents the cost during January. In this month the load factor was fifty-nine, as against forty-six for the year, and it will be noticed that the labor is reduced to less than the standard. The reduction in the total cost for this month, as against the yearly, is also apparent, and this is due principally to the reduction in labor.

It will be seen that the coal expense is but slightly less, and seems not to be much reduced by the increased load factor. The explanation of this lies in the fact that the station is tied in with others, which keeps its load from fluctuating even on the low load factor. This will be still further exemplified by referring to a light month; the column at the right of the group gives the costs for September, during which the load factor was forty-three, as against fifty-nine for January. The coal expense is still further diminished, and by reference to the table will be found to be due to an increase in the efficiency of the station. This might be found to be on account of not having to force the boilers. The increase of labor due to the low load factor is to be noticed.

I wish to say at this point that it is impossible for me in the limited time to give you more than a general idea of the large number of interesting facts which may be obtained by careful study of the tables.

Plant No. 2 is somewhat larger than the last, and is equipped with two 1,000-KW. generators direct connected to compound condensing engines. It has also economizers and heaters. Its costs are in column No. 2. In looking at the yearly average it will be noticed that the total costs rise above the standard, which is due to an increase in labor and general expense. Coal, as before, is the same, the decreased efficiency being balanced by the lower price per ton. Examining the table with a view to accounting for the increase of labor we find the load factor approximately the same as standard, but an increase in the number of men per 1,000 KW. This is accounted for by the smaller size of the station. General expense is greater, as would be expected. A glance at the shaded diagram representing the heavy month for this station gives a nice illustration of the effect of high load factor, which is fifty-one, as against thirty-three for the year. It is to be noticed that the coal is practically the same, the reduction coming in the other two items. This brings the total cost for the month below standard. In the light month, with a low load factor of 28 per cent., the labor increase is very apparent.

I shall now present the costs of operation of a large station. Its equipment consists of six 1,200 KW. generators direct connected to triple condensing engines, two 1,500-KW. generators direct connected to compound condensing engines, and an auxiliary plant of forty 62-KW. generators belted to compound non-condensing engines, and only used in case of emergency. Economizers, heaters and electric feed pumps complete the important part of the equipment.

Group No. 4 indicates the costs for this station. The yearly average shows that we are approaching standard figures in labor. This item is not much less, as the units are only of slightly greater capacity. Load factor, rate of pay and men per 1,000 KW. correspond very closely with standard. The general expense and coal bring the total somewhat higher. General expense is high on account of the heavy repair account. The station is about eight years old and repairs are heavy, due to replacing of worn-out parts. The decrease in efficiency, as shown by pounds of coal per KW. hour, might be shown by a test to be due to old boilers.

The plants just considered have all been direct connected. Station No. 5 is a belted plant a little more than one-half the capacity of the standard, equipped with seven 340-KW. generators belted to a countershaft, to which are belted three triple condensing engines, the auxiliary apparatus affecting the economy of the station being economizers and feed water heaters. Diagram No. 5 represents the costs of a year, and also for heavy and light months. During the three periods the coal expense remains about the same, but there is considerable variation in the other items, due principally to the change of load factor.

Notwithstanding the high load factor, 52 per cent. of the labor for the year is still above standard. This would be expected from the multiplicity of parts to look after in a belted countershaft station. The reduction of general expense and labor in the heavy months is due to the load factor of 64 per cent.

Diagram No. 6 represents the cost for a belted plant of about one-fifth the capacity of standard. Its equipment is twelve generators belted to four simple high-speed non-condensing engines. There are feed water heaters, but no economizer. High coal consumption is the feature of this diagram, the cost of fuel alone for the year being equal to the total operating expenses for standard. Labor is also high, and the total cost of power per KW. hour is nearly double the operating expense of standard. This station furnishes a good illustration of the effect on the cost of power of a simple non-condensing belted equipment. It is to be remarked also that this plant has the benefit of a high load factor.

It will now be interesting to turn our attention to a small direct connected station, which is numbered one. This operates about thirty cars. It is equipped with three 200 KW. generators, has compound condensing engines, heaters, but no economizers. It does not feed in with other stations, as do those which have been previously mentioned, and has a very fluctuating load, as may be imagined in the operation of so small a number of cars. This station is just one-sixth the size of the standard, and it will be noticed that the column representing its operating expenses is about twice as high. The great increase is in the labor, although the station is operated by a corporation which has had a vast amount of experience in railroad work. Can we account for this increase in labor? By referring to the table we find the rate of pay of men is practically the same as standard; the load factor is low, 22 per cent., as against 33.

Referring to the heavy month for this station, which has the benefit of a 30 per cent. load factor, we find that the labor is reduced, but it is still a long way from bedrock figures. The examination of the table discloses the fact that the increase comes in the men per 1,000 KW., being about 2.5 times the standard figure. The station records show the following men operating: On the first shift, two engineers and one fireman; second shift, one engineer, one oiler and one fireman; third shift, one engineer and one fireman. Can this number of men be reduced? In a station whose equipment requires that the boilers be hand fired it is, to say the least, difficult to imagine that the boilers could be operated with less than one fireman per shift. The secret then for the large number of men per 1,000 KW. lies in the small number of KW. capacity. These same men could look after a station of greater capacity.

I shall next give the costs on plant No. 12, whose figures are presented in Table No. 2. This plant is about one-third the size of the standard. It does not feed in with other stations. Its generators are belted to three tandem compound condensing engines, which operate under steam pressure of 110 lbs. It has water tube boilers averaging four years of service, heaters, but no economizers. A good quality of bituminous coal is used, which costs $2.93 per ton. By reference to the table it will be seen that this station produced power to the extent of 23 per cent. of its capacity during the past year at 1.49 cents per KW. hour, including fixed charges, the operating expenses alone amounting to a little over 1 cent. The total cost of operation for the year was $23,000, of which $13,610 was for coal. Water costs this station nothing, and the labor was about one-half the coal bill. By referring to the diagram No. 12 it will be seen that the coal and labor are both much higher than the standard, and if standard performance had been reached a saving of $10,000 would have been made in the operating expenses for the year. An analysis of the items is given in column No. 12 of the table, and by comparing with the standard the differences may be readily seen. I do not wish to be understood in making these comparisons that it would necessarily pay to make the changes required to effect this saving, my present idea being to bring clearly before you the differences.

Station No. 13 is an interesting combination of cheap coal, simple non-condensing engines direct connected to the generators, together with a high load factor. Its capacity is 70 per cent. of the standard, the major part being three 800-KW. generators; the smaller unit is 200 KW. It produced power to the extent of 42 per cent. of its capacity at .96 cent per KW. hour, inclusive of depreciation and fixed charges. The depreciation is charged in at 5 per cent. on a capital expenditure of about $60 per KW. The total expense for the year was $92,617.28, which is made up of—

Labor	$15,453.25
Repairs and renewal of steam plant	1,839.69
Repairs and renewal of electrical plant	56.71
Fuel	44,780.94
Water	4,405.40
Oil, waste and lubricants	1,881.53
Tools, appliances and supplies	634.23
Taxes	1,945.65
Insurance	2,146.94
Interest	11,472.94
Depreciation, 5 per cent. on $160,000	8,000.00
	$92,617.28

The analysis of these items is given for comparison with standard in column No. 13 of Table No. 2. The diagram shows labor for this station to be equal to standard, principally on account of high load factor, the other differences are also apparent. It is interesting to note that the road operated by this power station used on an average about 1.3 KW. hours per car mile. The total car miles for the year were 7,207,308, about 10 per cent. of this mileage being trail cars. There are other interesting data about this road which time will not permit me to review.

Plant No. 15 is an interesting example of what a multiplicity of units will do for labor, the figure being 6.3 men per 1,000 KW. The effect of this would be much more apparent on the diagram were it not for the high load factor and low rate of pay.

Plant No. 16 is of 1,600 KW. capacity. The cost for power for past year was $53,000. Load factor is the same as standard. Standard operates to produce about double the output for the same figure.

Station No. 28 is 1,400 KW. capacity, has slow speed condensing engines, heaters and economizers. The feed water leaves economizers at the high temperature of 258 degs. The engines are simple, belted to the generators and coal costs but $1.63 per ton.

Plant No. 29 is a compound condensing slow speed belted station of 1,900 KW. capacity, and feeds in with another station. The coal costs $3.86. Plants Nos. 30 and 31 are operated by the same corporation as No. 29.

No. 32 is a combination of two power houses feeding into the same system. These stations are interesting, because these costs are for the past year, and since then these two stations, as well as smaller ones operated by the same company, have been consolidated into a large water-power plant, from which power is transmitted at 13,000 volts. The two steam

stations shown in column thirty-two have five triple expansion condensing engines. This road operated on about 1.4 KW. hours per car mile. The coal costs $3 per ton. The water-power plant which replaced the steam has not been in operation long enough to enable its cost to be given.

Station No. 33 has rather a tall column, due principally to its low load factor of 16 per cent.

Station No. 34 operated at a lower cost than standard on account of the high load factor, 57 per cent., reducing the cost of labor, and low price of coal, $1 per ton.

No. 35 is a plant of 1,200 KW. capacity, interesting on account of the fact that it has but one unit. It operates with 2.1 men per 1,000 KW. a load factor of 37 per cent., coal costing $1.24 per ton. Its costs are quite a little lower than standard.

No. 37 is a record breaker in the opposite sense. It is of slightly greater capacity than No. 35, but has three engines and eleven generators, which require eight men per 1,000 KW. capacity. It has a load factor of but 11 per cent. during 151 days from January 1 to May 31, 1898. The effect of this on the cost of labor is very apparent.

No. 40 has a capacity of 9,200 KW. It is direct connected, has economizers and compound condensing engines. Anthracite coal is burned, costing $1.60 per ton. This plant operates at less than standard figures.

No. 42 is a belted plant, compound non-condensing engines, heaters, but no economizers. It has a good load factor, but the effect of the belted and small units shows in all three items.

No. 43 is a combination of alternating and direct current apparatus. It has a low load factor of 15 per cent. the effect of which is noticed on the labor.

No. 44 is a 6,000 KW. station, and, although belted, has large compound condensing engines and economizers, which, with coal at $1.60, brings the cost of fuel below standard figures.

It will now be instructive to take a general survey of the shaded diagram for all stations in Table No. 2. No. 37 towers above all the rest. Standard is at the extreme left. Coal in No. 37 is greater than the total operating expense for standard. This station pays but $1.75 per ton, but it uses 7.3 lbs. per KW. hour. Compare this with No. 35, about the same size plant, paying $1.24 for coal and using but 4.7 lbs. per KW. hour.

I can hardly ask you to compare the labor, but it is easily seven times as large in No. 37 as in No. 35. The load factor of 11 per cent. as against 37 per cent. would make this item three times as great, and men per 1,000 KW. 8 per cent. as against 2.1, would again increase the cost of labor three times. The higher rate of pay in plant No. 35 prevents the discrepancy being greater.

Let us look along the line for high coal cost. No. 16 seems to bear off the palm in this respect; $3.30 ton and 5 lbs. per KW. hour account for this. For strikingly low costs we have Nos. 34, 35 and 40.

But I am afraid that I hear somebody remark that I am making comparisons that may result in unfavorable criticism, and that I promised not to do, and therefore I will let the diagrams and tables speak for themselves, and assure you that they will reward careful study.

Tramways in Paris.

Paris is affording an example of the great development in tramways, says an English contemporary. The city is already well served with omnibuses, and has tramways driven by steam, electricity, cable and horse traction. The Conseil General of the department has just sanctioned schemes for three dozen new lines, providing better communication between the center of the city and the suburbs. The cars will be run by mechanical power and will pass through some of the finest boulevards and most crowded streets.

THE APPLICATION OF THE ELECTRIC MOTOR TO SMALL INDUSTRIAL PURPOSES AND ITS EFFECTS ON TRADE AND ON THE COMMUNITY GENERALLY.*

BY ALFRED H. GIBBINGS, M. I. E. E.,
Electrical Engineer, Bradford, Eng.

The electric motor is rapidly becoming the most favored medium for the transformation and transmission of energy for all industrial operations whether on a large or small scale. This is due to the paramount advantage it possesses over any other method of utilizing potential energy. These advantages are well known to electrical engineers, but indifferently appreciated by a large number of mechanical engineers, and almost unknown by the general manufacturer and tradesman. To the last of these three, the general manufacturer or tradesman who is using machinery driven at present by steam or water power, the electric motor must in the days to come prove of exceptional value; and yet, strangely enough, very little effort has hitherto been made either by the motor maker or by the managers of electricity supply undertakings to open up this very wide and lucrative field of enterprise. There is no necessity to enumerate here the many excellent and distinctive features which the electric motor possesses. The intention in this paper is rather to consider the reasons why its application up to the present time has been confined to a few special trades and manufacturers. We are familiar, for instance, with electrically-driven pumps, electric hoists and cranes, electrically driven machine tools, and electric power transmission in works—cases in which the generation, transformation and application occur practically under one roof. Many manufacturers and constructional engineers, wisely and readily incurring additional capital outlay with the object of securing more economical production, have adopted electric motors, which do not entail the use of endless and power-absorbing shafting and countershafting. As yet, however, it cannot be said that the electric motor is in general use, or scarcely other than just past the threshold of its future domain. I shall endeavor to show how large a sphere of influence it is destined to fill. The smaller producer and tradesman, to whom motive power in some form or other is essential, and who feels more acutely than his larger *confrère* the effects of competition, has in the great majority of cases still to put up with very much more cumbersome and very much less efficient means of power production. Almost every town with any pretension to size and importance has its own large staple industries, as well as many minor industries and businesses, requiring the use of other power than hand power. There are also some handicrafts which are at present unavoidably confined to hand power, because steam, gas, oil and hydraulic power are each and all inapplicable. There can be little doubt that the electric motor would be welcomed and readily adopted in these cases if only its simplicity and adaptability were known and understood. I will give a somewhat full, though by no means exhaustive, list of these trades: acid manufacturers, agricultural implement makers, automatic electric signs, back and vat makers, bag makers, aerated bread makers, basket makers, bicycle makers and repairers, boiler makers, book binders, boot makers, boot polishing, bottle cleaners, bottle makers, box makers, brass finishers, brush makers, cabinet makers, carpenters, carpet beaters, coach builders, coffee grinders, coopers, cutlers, cranes, dairymen, dentists, engineering workshops, engravers, fans for ventilating and other purposes, forage cutters, forced draught, founders, grain elevators, hoists, hair-brushing machinery, laundries, lifts, lithographers, mill-wrights, musical instrument makers, oil refiners, opticians, organ builders, organ blowing, packing-case makers, paper makers, pianoforte makers, picture-frame makers, presses, printing machinery, pumping, racket makers, rope makers, sack makers, saddlers, sausage makers, saw makers, saw mills, scientific instrument makers, seed crushers, sewing machines, shop fitters, smallware manufacturers, smelters, smiths, snuff manufacturers, soap makers, stick makers, stuff manufacturers, sugar refiners, surgical instrument makers, theatrical machinery, timber merchants, tinplate workers, tobacco cutters, tool cutters, tool makers, toy makers, turners, umbrella makers, undertakers, watch makers, wire drawers and workers, zinc workers, etc. Other special and local industries will occur to you without enumeration which can be placed in the same category.

The advantages of driving electrically in some of these cases are of a very distinctive character, and it will be well to consider briefly one or two prominent examples.

Boiler Makers.—The practice of drilling all rivet-holes in boilers with the overlapping plates *in situ* is an operation which is much more rapidly, readily and economically performed if the drilling machines can be brought to the work instead of taking the shells to a fixed machine tool and there adjusting them for every fresh set of holes to be drilled.

Book Binders, Boot Makers, Cutlers, Presses, Saddlers, Saw Mills, Smiths, etc.—These trades are instances in which several machines are frequently employed, but of which intermittent use only is required. By any method of driving, other than by electricity, it is incumbent to employ lines of shafting and countershafting, and to keep these in continual motion in order to use any one machine when required. In such cases, by direct coupling to the machine to be driven, and by its unequalled facility for starting and stopping, the electric motor has unique and all-important advantages.

Letterpress and Lithographic Printing.—This class of machinery has been successfully operated for upwards of two years by electric motors applied direct to the main driving shaft of the machine or by toothed gearing. Since the first attempts were made many improvements have been introduced, until at the present time nearly all the leading houses in the trade have either adopted the system of single-machine driving in its entirety, or some such modification of it as best seems to suit their particular methods of working. It is doubtful if printers realize the immense loss that occurs by the old method of driving. Wherever the system of shafting and belts is used to transmit the energy generated by the driving engine there is a great loss of power, not only so, but a mass of machinery and gearing has to be kept wastefully running whilst possibly only one or two machines may be utilized. In one case where tests were made it was found that the shafting and belts absorbed 56 per cent. of the actual power generated by the engine. In this industry the extremely steady and even motion imparted by the rotary action of the electric motor is also an important feature.

Cranes and Hoists.—In almost every town there are warehouse and other cranes, and passenger and goods hoists, in general use. The advantages of the electric motor for these purposes are (1) the possibility of placing the motor close up to its work, (2) direct coupling or reduction gearing of high efficiency, and (3) the economy resulting from the power used being practically proportionate to the work done.

There is no need for me to give you further examples in detail. The application of ordinary mechanical tests for efficiency, and the experience already obtained by the substitution of electric motors for other methods of power production, have proved beyond doubt its exceeding adaptability and superiority. Notwithstanding all this, however, many obstacles yet remain to hinder its general adoption

* Paper read before the British Association, Section G, Bristol, Eng., Sept. 12, 1898.

by what may be termed the commonalty of the manufacturing world, and among the principal may be mentioned the following:

1. The extreme aversion to innovations which characterizes the industrial world in this country especially.

2. The existence of other motors in good working condition.

3. The unsuitability of alternating currents of electricity for motors where the power required exceeds 2 HP. or 3 HP.

4. The want of capital to lay out in new machinery.

5. The want of confidence in the electric motor by the non-technical manufacturer.

The first and second points do not require any further commentary or elucidation, and I shall therefore dismiss them without more observation. With regard to the third point, it is much to be regretted that the alternating-current motor is not yet capable of doing the same work as a continuous-current motor. The energy required to operate either type must, of course, be derived from some source—usually a steam dynamo—from which distribution mains carry the current in any direction; and as this is the most efficient method known of transmitting energy and the motor the most efficient medium for transforming it into useful work, the principle has been applied in the workshop as well as for public supply. There is no need to dwell upon the advantages of the centralization of steam power, nor upon the universally admitted fact that electricity for power purposes can be supplied from public lighting mains at a very low cost. But in addition to these there is one equally important advantage of deriving power from public mains from the user's point of view—I refer to the actual resultant taken on the average of the varying loads, which is characteristic of the electric motor, and the facility for instantaneously switching "on" and "off" as required. This feature is illustrated in the curve shown which has been taken from the most modern machines. It will be seen that the maximum horse-power was 6.4, and the duration of time 18 minutes, which, if the maximum power had been a constant load, would represent approximately 2 horse-power hours. But after the resultant had been carefully obtained with a planimeter, the actual horse-power hours are found to be 1.06. This difference between the maximum horse-power required and the mean horse-power used is rarely taken into account or even understood by many small power users—it is a most difficult thing to get them to appreciate it.

The chief obstacle to the more rapid adoption of electric motive power, especially in the case of small tradesmen, throughout the country is undoubtedly the want of capital to purchase the necessary motor; but where the power to purchase exists, the buyer will probably have little or no experience or knowledge of electrical matters to guide him in his purchase; if his means are at all limited he will be tempted to venture on a cheap line, and become the dupe of those who simply make to sell. The solution of these difficulties—which to my mind appears the most satisfactory, because it is the one fraught with the greatest advantages to all concerned—is that the owners of electricity supply undertakings, whether a public company, municipality or other local authority, should themselves purchase good, reliable motors, and let them out on hire. Antecedently this scheme may appear a sort of parental regime, but it is suited to present circumstances at any rate, and experience proves it to work well. Unfortunately, all local authorities have not got powers to borrow money for this purpose, although it appears from the Electric Lighting and Public Health Acts that borrowing powers may be granted by the Local Government Board for works of a permanent nature. Electric motors do not yet come within that category, although gas-stoves do, a legal decision having been given in their case. All future municipal parliamentary bills should therefore contain clauses which would confer such powers and secure freedom of action in this respect. I do not propose here to run into elaborate details with regard to terms or general scheme of hire, but I may say that in Bradford we have found a rental charge of 10 per cent. upon the initial cost of each motor to be amply sufficient. This is made up of 3 per cent. for interest, 3 per cent. for sinking fund, and 4 per cent. for depreciation and contingent expenses. The Bradford Corporation inaugurated their scheme of hiring (in which also aro lamps are included on similar terms) in November, 1896, and the following table will show the extent to which these facilities have been appreciated:

Year.	Number of motors supplied from Corporation mains.		Board of Trade units sold per annum
	Owned by consumer. Not on hire.	Owned by Corporation. On hire	
1885	35	nil.	35,919
1886	23	7	84,972
1887	14	39	117,176
1888 (Six months only).	6	22	63,820.

From this table it will be seen that the increase in electricity supplied for motive power in 1896, in which year the hire system had been in operation for two months only, was 19,053 units; in 1897 the increased sale over 1896 was 52,204 units, and in the present year the increase is likely to be 62,834—or a sale of 180,000 units, or 53 per cent., over 1897.

Hitherto the supply has been confined to small power uses, such as cranes, hoists, fans, pumping, aerated water making, electric advertisement signs and similar purposes. During the last month, however, so popular has the electric motor become that applications have been received from a large spinning and weaving firm, two foundries for blower purposes, an engineering shop requiring 50 HP. and a saw-mill requiring about 20 HP. I referred a moment or two ago to the want of confidence of the small power user in the electric motor; that confidence, however is soon gained. It is gratifying to be able to state that several consumers in Bradford who originally applied on the hire system, and at the time with much trepidation and many inquiries, have since decided to purchase the motors outright. The accompanying table has been compiled from replies to an inquiry which I made recently of each municipal electrical engineer where the continuous current system has been adopted, and from it may be gathered the extent to which electric motors driven from electric lighting mains have been employed. The figures given are up to the end of 1897:

Town.	Population.	Number of motors supplied.	Total HP. of motors.
Aberdeen	140,000	14	65
Bradford	231,260	119	470
Brighton	122,310	100	......
Belfast	320,000	......	165
Birkenhead	110,000	4	15
Bury	63,000	5	12
Blackpool	40,000	7	7
Burnley	90,000	8	32
Chester	87,100	20	70
Dewsbury	29,847	4	16½
Dundee	169,000	15	20
Edinburgh	295,000	167	343
Glasgow	750,000	37	131
Hull	213 000	14	46
Lancaster	38,224	28	80
Liverpool	641,063	57	152
Manchester	505,368	257	696
Norwich	101,000	61	120
Nottingham	213,877	18	50
Oldham	148,000	11	60
Southampton	90,000	18	23
Shoreditch	124,000	31	434
Sunderland	147,000	23	240
Wolverhampton	92,000	2	8
Whitehaven	20,000	....	......
Walsall	72,000	7	13½

I have endeavored in this paper, and in the necessarily limited time and space at my disposal, to place before you the outlines only of a method of extending the adoption of electric motive power by the general manufacturing community. Those who have the management of public electricity supply undertakings know full well the value of the electric motor as a factor in the reduction of the working costs, which is also the principal argument for the combined working under one roof of electric lighting and electric tramway systems. But there are other and probably greater effects which the electric motor will produce with its more complete adoption in the near future—I refer to the beneficial effects upon the trade and productions of the country, and the hygienic and social effects on the community generally. In the first of these aspects it is possible to foresee the revival once more of a number of small and independent industries—such as existed, but under very different conditions, in former years. The possibilities are already being grasped by the artisan in France, Germany, Switzerland and the United States. By the aid of the electric motor he begins to find that he can at least hold his own in competing with immense manufacturing concerns and combinations; he has a practically unlimited available power at his own door—which is a great boon to the artisan, and one which offers him an inducement to become his own master. In a very small and limited degree the gas-engine has already accomplished something in this direction, but its many imperfections, its cost, and the fact that it has never been available on the hire system, have kept it more or less in the background. The effect of hiring-out is thus mutually advantageous and its natural tendency is to create fresh demands; in fact, the municipality which includes this scheme in its electric light undertaking offers a great inducement to the influx and establishment of new industries within its area. With a more complete return to a multiplicity of industrial operations, there may also revive some neglected trades—such as those which have passed from us to other countries, and which now form our imports. From a hygienic point of view the electric motor is far and away the best; it is cleanly in its working, gives off no deleterious gases, and displaces the boiler and smoky chimney. One of the ultimate results must also be the raising of the status of the working part of the community. By becoming his own master the artisan gains self-respect, becomes more resourceful, and therefore a more important member of society; and the more intelligent interest which he will display in his business must appreciably affect the general welfare of the country.

ELECTRIC SIGNALING IN THE GERMAN NAVY.

BY BEAUMONT PONTIFEX.

A system devised by M. Kaselovski, which is worked by various combinations of incandescent lamps, has been adopted for the vessels of the German navy. The whole design of the apparatus is based on the following considerations: (1) the use of *one* switch key only; (2) moving the key from one signal to another must break *both* poles of circuit; (3) great mechanical steadiness; (4) immunity from damp.

The most important item is the switch. On large vessels this is carried on a pedestal on the bridge, but on torpedo boats, etc., it is fixed on the after side of the conning tower. The switch is contained in a cylindrical brass case, which carries on its base a flange for bolting to supports and a socket-union for the seven-pin end of the flexible cable, the flange being left hollow for the leads from source of supply, which is usually the incandescent lighting plant of the ship. The top cover of the switch contains the indicating disks, which are made of colored and marked glass to correspond to the prearranged signals and give the proper direction to turn the key to indicate same. These glass disks are arranged in a circle round the edge of the cover, and are lit by an incandescent lamp inside the case.

The actual contacts of the switch consist of plun-

gers pressing against recessed gunmetal disks, fastened on a central spindle and insulated from it. The plungers are driven against the disks by spiral springs, but their travel is limited by collars, so that when a recess in one of the disks is brought opposite a plunger contact is broken. The recesses are so arranged that by turning the key the circuits are by turns closed and opened, whereby, according to arrangement, one, two or three incandescent lamps out of six are lit in succession. There are also two plungers on the opposite side of the disks, which throw in and out of circuit one, two, or three lamps used as a compensating resistance. Two separate plungers pressing on the lower part of the spindle serve to break contact on the common return wire whenever the spindle is lifted to allow the key to move from one contact to another. The entire switch is easy to handle, and is quickly taken to pieces for repairs or renewal of springs, plungers, etc. A seven-core flexible cable is used, one core being a common lead to all lamps, the other six being individually connected to the opposite pole of each lantern. There is a central steel wire to add strength to the cable, and the whole is thickly braided.

The lanterns are two-light fittings, the upper half white and the lower red, carried in a frame of flat iron. The glasses are of the usual "well" pattern, secured by rubber washers held in an iron rim by bolts. The lamps are hung one over another at fixed intervals on the mast, so arranged that the white lights are on top and the red underneath them. Each lantern has a two-way socket at the side, to which is screwed the connecting plugs on the cable.

When not in use, the entire gear is stowed in an iron box resembling both in shape and size the familiar household sanitary dustbin.—*Electrical Engineer, London.*

EQUIPMENT AND MAINTENANCE OF ELECTRIC CARS.*

BY M. S. HOPKINS.

An ancient king of fable offered a rich reward to the courtier that could tell a story that would last forever. To him that undertook it and failed the price was his head. Were this merry monarch living to-day he might gratify his wish by asking, "how shall I best manage my street railway?" and all his newspaper editors, councilmen and other subjects would at once undertake the task, for it is a matter of common knowledge that everybody can manage a street railway much better than it has ever been managed.

The modern king of finance is daily asking this question of his hired subjects, and unless the answer is expressed in dividends the story is at an end and the head of the manager is the penalty of failure. To attempt to discuss all of the various elements entering into the composition of a successful street railway would be a continued story, and not within the province of this paper. What is the best electric equipment to purchase and how can it be made to render the best service at the least cost, is the question which daily confronts the street railway manager, and one on which he is constantly seeking advice. There can be no answer which is applicable to all street railways, and no especial merit is claimed for the views set forth other than that they are the result of experience and born of repeated failures and successes.

CAR EQUIPMENT.

No fixed rule can be laid down for the selection of equipment, as climatic conditions, character of traffic, frequency of headway, conditions of roadway, municipal regulations and grades are all elements which determine what the equipment may or should be.

ELECTRICAL EQUIPMENT.

In the selection of the electrical equipment the main point is to secure equipment of ample capacity and proper design for the service required. In a railway motor, the mechanical and electrical features which influence its maintenance should receive very careful consideration. The bearings should be large and lubricated by oil from below and cup grease from above, and so designed that the drip from the bearings will fall outside of frame. The armature should be so constructed as to permit the shaft being pushed out without disturbing the commutator and winding.

I am glad to note that the importance of light weight and slow peripheral speed of armature has been recognized in the recent design of railway motors. The inertia or flywheel capacity of the armature should be the smallest possible, consistent with the work required. Engineers differ as to the best method of suspension. From a theoretical standpoint the cradle or side bar suspension has the lead. The dead weight is largely removed from axle, thereby eliminating to some extent the hammer blow on rail joints, decreasing the wear on axle brasses and s curing the better alignment of gears; yet, in practice, the nose suspension is still preferred by the writer, as the car starts more smoothly—the weight of motor on spring supports overcoming the jerk and quiver so common in other methods of support. The specifications for railway motors as drawn up by leading manufacturers of to-day amount to practically nothing, and I would suggest that the purchaser of motors in his specifications clearly define the rating, heat limit and efficiency.

The series parallel controller is in most respects a satisfactory device, the chief objection being the narrow range of speed on running notches. Specifications for resistance should provide that the last two points of resistance be of sufficient capacity to allow of their continued use as running notches, especially where cars are operated in city service.

There are several types of magazine fuse boxes or cutouts and single cutouts using a special fuse which possess a number of points of merit. Without going into detail, it is the opinion of the writer that under average conditions the standard magnetic blowout fuse box, using a link fuse, is preferable.

Where side sills are plated on outside with steel plates, all season cracks should be thoroughly filled with a thick mixture of lead and oil, and entire surface given a heavy coat of oil paint before plate is put on. It is hardly necessary to say that all joints should be well leaded and protected from moisture. A heavy steel roof rafter in one piece should be put in at every post, and a saving in maintenance will be made by having platform floors of oak or maple. The trolley stand should be mounted on a trussed support, which will distribute the strain to the ends of car as much as possible.

Ash seems to be almost universally used in post and light framing of cars. This is probably due to the difficulty in securing the grade of oak necessary, the lighter weight of the ash, the greater ease with which it is worked. In spite of these difficulties, oak is far preferable, being stronger and more elastic, and will give a far longer life.

TRUCKS.

Under the average conditions 22-ft. closed car or eight reversible seat open-car body should be the limit for a single truck. Although there are single trucks which will carry a longer body fairly well, yet the increase in maintenance will in most cases warrant the use of double trucks. The local conditions should govern the type of double truck used, the bolster type in most cases being preferable for long cars on high speed suburban service, while for city service, where heavy grades and quick starts demand maximum traction, and short curves make it necessary for the wheel to turn under sill, the bicycle type must necessarily be used. This type of truck is no longer an experiment, and while they possibly require more careful inspection and adjustment, very efficient service can be secured from trucks of this type.

Trucks should be made up of a small number of parts, cast and malleable pieces should be the lightest consistent with strength. The springs should be so arranged as to prevent oscillation and give an easy riding car under all conditions from no load to full load, and when the style of truck is of such design as to prevent the use of an under truss, the spring base must be exceptionally long and the end springs so arranged as to relieve the strain on the car sills.

The brake mechanism should be so designed that the strains will be equally distributed on all parts throughout its range of movement. The pins should be of ample size to provide for wear. The slider method of support for brake beam will be found more satisfactory than the loop support. The minimum amount of friction should exist between brake staff and shoe, and release springs as light as possible.

CAR BODIES.

For years car builders have attempted to devise a car body which would be equally durable in both summer and winter, but judging from the character of equipment now in use on the majority of roads, such a car has not yet been produced. The combination car with movable parts is not satisfactory for winter use, is troublesome, noisy and cold, and is lacking in many of the essential features of the open car for summer service. The open cross-seat car of the barge type, with running boards on the side, seems by far the most desirable type of car for summer service, affording the largest seating capacity and the best facilities for receiving and discharging passengers, which is a great advantage in city service. Considering all features, the box car with side seats, large windows, wide end door to the side of center, roomy platform and vestibules closed on one side, seems best adapted to the average condition of winter service. While the vestibule type closed on one side is not so convenient for the handling of large crowds, yet the additional safety afforded on double-track roads should receive full consideration even at the expense of convenience. In localities where winters are accompanied with snow fall and freezing weather, the vestibule affords protection to passengers, and motormen and conductors are able to render very much more efficient service.

The long car body seems to be growing in favor with the railway manager, due to the comparatively small increase in operation in comparison to increased carrying capacity, and its allowing of the increase of headway or decrease in number of cars run, resulting in a large decrease in operating expense per passenger carried.

The purchaser of car bodies should have a clear conception of the details of car construction, and specifications should clearly set forth the essential features, minor details of interior finish and decoration being left to the manufacturer.

In the construction of box-car bodies, the trusses should be as deep as possible and great care taken to secure a perfectly rigid fastening at end of sill, as the slightest deflection throws an undue strain on joints and framing of car body.

Each car should be equipped with a thoroughly reliable lightning arrester. The points to be noted in selecting this device are as follows: The kicking coil should always be installed; the air gap should be as small as possible; there should be a positive and quick device for interrupting the current after discharge, and one which will not be injured by discharge; there should be a non-inductive resistance in the main circuit which will limit the flow of current and thereby prevent the opening of the circuit breaker at the station when several arresters operate at the same time.

One of the most puzzling problems brought before the manager to-day is the amount which should be expended in the maintenance of old equipment before it should be replaced by new. To the average master mechanic this would seem a simple problem of mak-

* Read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

ing a careful estimate of the difference in cost of maintenance of the old and new equipment, due consideration being given to the interest on money invested in new equipment and its increased efficiency. Still after the master mechanic has conclusively shown that by putting in new equipment a marked saving can be made in cost of operation, the manager has to consider the financial condition of the property, the advisability of increasing the investment, the possibility of doing so, and whether there are not other departments of the road where a greater saving can be made by increasing the investment. One should go slow in putting in new equipment, as new apparatus may at first seem to be void of the main defects inherent in old equipment, yet when put in operation other defects occur which under the varying conditions may prove even more disastrous than the old.

MAINTENANCE OF EQUIPMENT.

The cost of maintaining equipment depends on various complex conditions, some of which are beyond control of the manager, and others for which he should be directly responsible. Heavy grades numerous railway crossings, sharp curves, dirty and unpaved streets, imperfect and poorly constructed equipment, long and severe winters, all affect cost of maintenance unfavorably and are beyond control of the manager. But the character of men who operate the cars, the manner of operation, the way in which repairs are made, the character of men engaged in repairs, and the material used, are the controllable elements and in most instances the chief features affecting maintenance.

CARE OF EQUIPMENT IN CAR HOUSES.

Generally one of the following three methods is used for daily inspection of car equipment, namely: inspection of cars for each trip, inspection of equipment at night by motor inspectors, inspection of equipment during the day by motor inspectors and repair men.

In regard to the first case, that of the trip inspection, I would say that in the present degree of perfection attained by manufacturers of railway equipment, trip inspection should not be necessary, and, excepting on interurban lines operating at high speed over long runs, is of doubtful value. It is expensive, requiring the services of an inspector who is necessarily a man of some ability for each line of cars. The period of time for making this inspection is necessarily very short, and the entire time is taken up in mere inspection—little or no opportunity being afforded in which to make repairs.

In regard to night inspection, the experience of the writer has been such as to absolutely condemn such a method as expensive, slovenly and unsatisfactory. It is impossible to make a thorough inspection of cars at night, no matter how well lighted the car house may be, and the efficiency of the work done by the men is very far below that of the work during the day. Therefore, when local conditions will admit, inspection of cars during the day seems by far the most advantageous.

We will assume a car-house station, from which twenty-five or more cars are operated. There is usually one general foreman in charge of this station. His duties are chiefly those of the transportation department, but he should be a man thoroughly conversant with the usual trouble which may occur in the operation of the equipment, and know how to direct minor repairs. It would be better, of course, if he were able to personally superintend the actual work of repairs, but it is usually very difficult to find men who are good mechanics and likewise efficient in the transportation department.

For making inspection and running repairs such as should be made in car houses, it is a safe rule to have one man to seven cars. It is important, however, to have in all car stations a man known as chief inspector of that division, who is thoroughly conversant with practical electrical and mechanical matters. This chief inspector should have under his care for inspection and repairs seven cars, and also have direction and supervision of the other two repair men who care for the remaining eighteen cars.

It is important that the responsibilty for the proper repair of cars be definitely located, as nothing is so demoralizing to the force of motor inspectors as to have a case of trouble arise and not be able to trace the responsibility at once to the proper source.

The duties of these men should be to make a daily inspection of every car assigned to them, starting first with their motors, examining the grease cups, the brushes, cleaning the motors, examining connections, etc. They should remove the covers from their controllers about once in three days and oil the cams very lightly with vaseline or grease, remove any blisters which may have appeared on the contact points and carefully examine the adjustment of contact fingers. Too much emphasis cannot be given to the inspection of all brake rigging, and very thorough inspection should be made daily from the brake-handle to the brake-shoe, and the brakes tried by inspectors before the car is placed in service. A broken brake-chain or worn-out shoe, a broken brake-clutch or a broken brake-pin are things that should never occur through neglect, and if an accident of this kind does occur, the cause should be immediately traced and the responsibility located. Economy in maintenance should never be exercised at the expense of absolute safety, and brake-chains, pins and shoes should be discarded long before the danger point is reached.

The general public forms its opinion of maintenance of equipment by the little things on the interior of the car, such as a screw loose in the back, a broken strip on the floor, loose register pulley, broken hand-strap, broken glass, rattling glass and hundreds of other little things which make the fittings of a car body. Repairmen and inspectors should be so trained that in passing through the car on their inspection they should note any little thing of this kind at once, and the rule should be that they stop and repair it at once, for if allowed to wait till some other time the repair is usually neglected entirely.

The actual repair work done by these inspectors should be all work possible to be done without the use of machine tools, or which, if done by them, will not require the loss of the car from service for a period of more than two hours.

If during this inspection the motor inspector discovers trouble which is beyond his ability to repair, he should fill out a repair slip and send the case with the slip at once to the repair shop, stating the nature of the required repair, assuming that the repair shop is run as a separate department from that of the car barn. If the nature of the trouble is such as not to immediately incapacitate the car for use, but which requires the services of the repair shop department, he should fill out the blank as above noted and send same to the foreman of repair shop, but this notice to the repair shop foreman should in no way release the motor inspector from the responsibility of the successful operation of the car. If the repair shop foreman is unable to take the car off the road at once, owing to press of work, it is the duty of the motor inspector to watch continuously the development of the trouble, and if at any time he thinks it has so advanced that car is not safe for successful operation he should leave the car out of service, and so notify repair shop foreman. If the latter is still unable to receive the car at the shop he should then make a personal examination of car and assume responsibility for its further operation.

The questions as to how often car equipment should be taken to the shops for a general inspection and overhauling, and to what tests the electric equipment should be given at the time of inspection, are subjects upon which electrical engineers widely differ. Considering the average conditions, and assuming that the equipment is in good condition, it is the opinion of the writer that the taking of cars to shops once every six months should maintain the equipment in good condition and assure its efficient operation.

(To be continued.)

Electricity in a Japanese Iron Works.

The *Elektrotechnischer Anzegier* contains a note to the effect that the iron and steel works in Yawatanura, belonging to the Japanese Government, are using electrical power to drive the individual machines. The electrical equipment, which is being supplied by Messrs. Siemens & Halske, comprises three steam dynamos of the continuous current type with internal poles, the aggregate capacity being 1,750 HP. Current is supplied at 250 volts to several hundreds of motors for various purposes, for cranes and motors up to 100 HP., pumps of various sizes, blowers, and for all kinds of machine tools. The works are also lit by electricity.

The Evian-les Bains Three-Phase Tramway.

On June 10 last, says the *Electrician*, London, a small three-phase tramway line was opened at Evian-les-Bains, a popular watering-place on the French side of the Lake of Geneva. The tramway leads from the Hotel Splendide to the Avenue des Sources, where the springs are. The hotel, although overlooking the avenue, lies at a higher elevation, and the line follows an S-like course, rising 67 ft. in a length of about 330 yds., a mean gradient of 6.8 per cent. The maximum gradient is 10.2 per cent., and the sharpest curve occurs on this part of the line, and has a radius of 49 ft.

A three-phase system was chosen as there was already a three-phase station eight miles distant; this system also having the advantage that the motors have no commutators requiring attention. The pressure at which the current is transmitted is 5,200 volts, the frequency is 50 cycles per second, and the same transmission line is used for light and power. A 30 kilowatt stationary transformer converts the pressure of each phase to 200 volts, this transformer also furnishing current to drive a 6 HP. motor for the pump of the hydraulic lift in the hotel. The two trolley wires are of 6 mm. hard-drawn copper, and are supported 11¾ in. apart on ornamental steel posts with brackets. The rails form the third conductor, and they are bonded in the usual manner. The line is single-track, and there are no crossings as only one car runs on it.

This motor car weighs 3.8 tons, has seats for eight, and standing room for six more passengers. The interior of the car is luxuriously upholstered and provided with a carpet, and two incandescent lamps are used to light it. The two headlights are also electric. A light two-axle truck supports the car-body, being fitted with one three phase motor only, whose normal output is 15 HP., although it can develop 25 to 30 HP. for a short time. The motor-shaft makes 750 revolutions per minute and drives a countershaft through spur-gearing, the countershaft being connected to the axles by chain-gearing. This arrangement is said to have been necessary to obtain sufficient adhesion. The field of the motor is stationary and the armature revolves, being connected to the starting resistance by means of brushes and contact-rings. Each platform is provided with a simple starting-switch and an emergency switch. The motor is in circuit both during the ascent and descent; in the latter case it acts as a brake, the motor running as a generator slightly faster than the speed of synchronism. If one of the trolleys gets off the wire, the motor continues to run as a single-phase motor; if both trolleys fail, the hand-brake must be employed.

A contrivance for strewing sand on to the lines is fitted at each end of the car. This consists of two horizontal cylindrical shells, one within the other, the inner one having a slit parallel to the axis. This

inner cylinder, which contains the sand, is turned with the slit upwards in its normal position, and when sand is to be strewed on the track it is revolved slightly by a hand-lever, thus tipping sand into the outer cylinder which is fitted with funnel-shaped orifices to direct the sand on to the rails.

The car makes about 60 double journeys a day, and its speed is 6½ miles an hour in either direction.

The permanent way and transmission line were built by the firm of Lombard et Cie. of Lyons, the motor car and electrical equipment by Messrs. Ganz & Co. of Budapest.

A Big Company Incorporated in Jersey.

The Jersey City *Journal* of the 22d inst. has the following announcement:

"A certificate of incorporation of the North Hudson Light, Heat & Power Company was filed in the office of Secretary of State at Trenton last Monday by Counselor Spencer Weart of this city as attorney. The capital stock is $2,000,000, divided into 20,000 shares of the par value of $100, and the principal office is to be on Bloomfield street near Fourteenth street, the present office of the Hudson Electric Light Company, which concern the new corporation has purchased.

"The incorporators are: Albert B. Carlton of Elizabeth, Frank M. Stillman of Rahway, Samuel Hathaway and George W. Waite of this city, David Young and George W. Roe of Newark, and Arthur K. Bonta of Hoboken. Each incorporator has subscribed to twenty shares of stock and the new company starts in with $14,000 capital paid in. Mr. Bonta is the present superintendent of the Hudson Electric Light Company, and it is stated will act as manager of the new corporation.

"The articles of incorporation state that the objects of the new company are to construct, purchase, lease, maintain and operate works, with all appliances, patents and appurtenances necessary thereto, as now or may hereafter be used for the manufacture and production, supply and distribution of electricity for electric light, heat, power or any other purpose, and for the manufacture and production, supply and distribution of heat and power by steam or any other method in Hudson County.

"The principal object of the new company is to enlarge the electric facilities in Hoboken and North Hudson. The present concern has been supplying steam for power to several factories near its plant, as a matter of convenience, and a clause has been inserted in the articles of incorporation to include that function.

"Vice-President David Young of the North Jersey Street Railway Company is one of the incorporators, and Messrs. Hathaway and Waite of this city are two of the other incorporators. The remaining incorporators are interested in electric light companies in various cities. Some time ago the Hudson Electric Light Company was purchased by the General Electric Company and the new corporation is a branch of the parent company.

"The old concern has been supplying power to the North Hudson Railway Company for the operation of some of its trolley lines, but it is not expected that this will be materially increased. The company has also been supplying, and will continue to supply the North Jersey Street Railway Company with power."

Motor Cars for Army Use.

Motor cars are being tried in the autumn manœuvres by the German army. Should they prove efficient, a number will be manufactured by the Government and one or two attached to each regiment.

THE ELECTRIC CONSOLIDATION.

Mr. Westinghouse's Statement.

On the 21st inst. Mr. George Westinghouse, president of the Westinghouse Electric & Manufacturing Company, made the following announcement on behalf of his company:

"The election this day of Roswell P. Flower and Anthony N. Brady as members of the Board of Directors of the Westinghouse Electric & Manufacturing Company, to represent the interests of the former stockholders of the Walker Company, completes the union of the interests of the Walker Company of Cleveland with those of the Westinghouse Electric & Manufacturing Company. The purchase by the Westinghouse Company includes substantially all of the outstanding stock and all but $850,000 of the $2,500,000 of the twenty-year bonds of the Walker Company, the $850,000 remaining a first lien upon the property. The recent sale by the Westinghouse Company of $3,000,000 of debenture certificates has erroneously been connected with this transaction. The entire proceeds of the sale of these debenture certificates were used in retiring the floating and other debt of the company as previously announced.

"The increase in the total yearly fixed charges of the Westinghouse Company, due to the purchase of the Walker Company, will be but a little more than the sum that the Walker Company has been expending annually in defending patent litigation instituted by the General Electric and Westinghouse Companies. The acquisition of the Walker Company will, by reason of the agreement of March 31, 1896, between the General Electric and Westinghouse Companies, put an end to this patent litigation and very large annual expenditure on both sides. The business of the Walker Company, as a controlled company of the Westinghouse Company, will be entitled to the protection of the patents of the Westinghouse and General Electric Companies, and will in all respects be subject to the agreement between these two companies in relation to patents.

"The Westinghouse Company regards the business and good will of the Walker Company as a valuable acquisition, especially as the Walker Company brings with it upward of $1,250,000 unfilled orders. The Walker Company has at Cleveland modern and extensive works, equipped with machinery capable of manufacturing the largest types of railway apparatus, and will, with the works of the Westinghouse Company at East Pittsburg, constitute a manufacturing plant second to none in the country. The capacity and profits of the two companies will be increased by carefully harmonizing the manufacturing and selling operations, and the direct savings thereby effected should exceed the fixed charges incurred by the purchase of the Walker Company. The shipments of both companies, owing to the large orders on hand, have been increasing during the past few months and exceeded $750,000 for August.

"The total fixed charges of the Westinghouse Company, including those due to the Walker purchase and the dividends on its preferred stock, will be $42,000 per month."

The New Officers of the Edison Illuminating Companies' Association.

The nineteenth annual meeting of the Edison Illuminating Companies' Association, which was held at Sault Ste. Marie, Mich., was concluded on the 14th inst. It was one of the most successful and interesting meetings ever held by the Association. The following officers were elected for the ensuing year:

President—R. R. Bowker, New York.

Vice-President—G. R. Stetson, New Bedford.

Treasurer—W. S. Barstow, Brooklyn, N. Y.

Secretary—Wilson S. Howell, Newark, N. J.

Executive Committee—Samuel Insull, Chicago; J. W. Lieb, Jr., New York; C. L. Edgar, Boston; Alex. Dow, Detroit; J. H. Vail, Philadelphia.

CANADIAN NOTES.

The Montmorenci Power Company of Quebec has been taken over by the Quebec, Charlevoix & Montmorenci Railway, which also owns the Quebec Electric Street Railway. Each original owner of stock in the Power Company, which furnishes light to the city and power for the electric road, receives an equal amount of stock in the new amalgamated company and the same amount of 5 per cent. debentures, redeemable in twenty years.

The hearing of evidence in the big electrical fight between the Royal Electric Company and the Lachine Rapids Hydraulic Company is now being taken before Judge Taschereau at Montreal, and promises to last some time. The Royal Electric started the ball rolling by first taking out an action for $5,000 against the Lachine company for general injury to their business by interfering with their circuit by crossing of wires and cutting the same, erection of poles, etc. This original demand was supplemented by an incidental demand of $50,000 for additional and sustained damages. The Lachine company took out a counter action for $105,000 damages to their business and for the circulation of injurious rumors that the Lachine company was suffering from the ice and that they would be unable to carry out their contracts and other injurious stories. These rumors, it is claimed, were of a nature to discredit and injure the company in the eyes of the community.

At the Montreal Royal Electric Company's annual meeting, the reports presented were considered to be satisfactory. The gross revenue was shown to have been $955,826, expenditure $636,057, interest and fixed charges $42,609, net profit $277,160. Four quarterly dividends have been declared of 2 per cent. each, equalling $120,000. Ninety thousand dollars were charged to profit and loss for reduction of assets in patents, $25,000 for depreciation of plant, and $31,992 for other reasons. It was shown that the company last year made 18½ per cent. on invested capital. A dividend of 8 per cent. has been paid yearly since 1891.

Since the commercial utility of electricity has been established, Canada has reason to congratulate herself on the enormous water powers available within her borders for transmission into manufacturing power. The falls of the Kootenay river, B. C., are the latest to be put in harness. The scheme contemplates the ultimate using of these falls, giving a capacity of 60,000 horse power, the present development on the middle fall (there being three falls known as the Bennington Falls) is 20,000 horse power. An interesting point that this work has demonstrated is that electrical energy may successfully be transmitted a distance of 30 miles. Almost simultaneously with the starting up of this plant the Cataract Power Company of Hamilton, Ont., under a generated pressure of 22,500 volts, carried a current to a transformer station 35 miles distant, for distribution.

Opening of the Y. M. C. A. Educational Classes.

At this time of the year many young men who are engaged in business in the daytime are making their plans to study in evening schools. These are the young men who think, and think to a purpose, and are advanced in business by reason of their increased value to their employers.

The Young Men's Christian Association conducts evening classes in commercial, scientific and language courses. At the West Side Branch of the Association, 318 West 57th street, New York, the opening exercises of the Educational Classes will be held in the auditorium on Monday evening, October 3, at 8:15 o'clock. Rev. J. M. Buckley, D. D, editor of the N. Y. *Christian Advocate*, will make the address of the evening, and music will be furnished by the Orpheus Mandolin & Guitar Club and Mr. J. Armour Galloway.

The West Side Branch is the most modern and best equipped building for Association work in this

country, and on the above evening all its rooms will be open to visitors.

Further information may be obtained of the secretary, Dr. D. E. Yarnell, 318 West 57th street.

Verdict of the Coroner's Jury in the Cohoes Collision Case.

The verdict rendered by the coroner's jury with respect to the casualty at Cohoes, N. Y., on Labor Day, when many persons were killed and many more injured by the collision of a railroad train with a motor car, is considered to be a just one and entirely consistent with the facts. They find that the Delaware & Hudson Canal Company's train was being propelled at a rate of about forty miles per hour in violation of a city ordinance; that the city had requested the D. & H. Company to place gates at the crossing, but the request had never been complied with. For this the company is censured, and demand is made that the city of Cohoes cause the arrest and punishment of the conductor and engineer of said train and that the company shall enforce in future the limit to the rate of speed; request is made that the Mayor and commonalty do all in their power to abolish grade crossings and in the meantime use gates. It is further found that the accident was caused by the criminal negligence of the motorman on the trolley car for not ascertaining whether or not a train was in sight before attempting to cross the tracks. The Troy City Railroad is severely censured for removing the demolished car, thus making it impossible to determine the condition of the brake at the time of the accident. It is also recommended that the Member of Assembly and the Senator from the district be requested to introduce into the Legislature at its next session a bill providing that a wreck in which life is lost shall remain until examined by properly authorized persons.

In accordance with these findings the engineer and conductor of the D. & H. train at the time of the accident were arrested and arraigned; both plead not guilty and were released upon their own recognizances for examination October 1. The conductor on the motor car has also been arrested but is now on bail, the bond being for $2,500. The motorman is still in too serious a condition to be taken from his home. Many suits have been commenced against the D. & H. and the Troy City Railroad by the relatives of those killed and injured at the time of the collision.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Albany, N. Y.—The Railroad Commissioners have granted the application of the New York & North Shore Railway Company for permission to construct an electric road from the terminus of the New York & Queens County Railroad, at Middle Village, L. I., through Jamaica, Flushing, Whitestone, College Point and Bay Side to Manhasset.

Americus, Ga.—There is a movement here looking to the building of an electric street railway. Plans and estimates for a belt line about five miles long have been made by a local engineer, but no organization has been effected yet.

Cranford, N. J.—The council has granted a franchise to the Westfield & Elizabeth Railroad Company to build a trolley road through the town. The company now has franchises for every foot of the distance from Elizabeth to Plainfield except through Roselle.

Denver, Col.—The board of supervisors, to which ordinances granting franchises are submitted for approval, have refused to confirm the franchise for a change of motive power granted the cable railway company which was passed over the mayor's veto by the board of aldermen.

Doylestown, Pa.—The Newtown Electric Street Railroad Company, which recently acquired control of the Langhorne & Bristol trolley road, has awarded the contract for the extension of this line from Newtown to Doylestown. This will make a continuous line of 26 miles from Bristol to the county seat.

Hartford, Conn.—The company organized recently under the Suffield & East Granby Street Railway charter intends to petition the Superior Court to have the name changed to the Hartford & Springfield Street Railway Company. George W. Dunham of Flemington, N. J., is president of the new company and the directors besides him are E. R. Gilman of New York, Noble E. Pierce and F. L. Fairbanks of Bristol and T. F. Welsh of Southington, Conn. Mr. Dunham organized the company for the completion of the road begun by Jesse W. Starr and others. Mr. Starr, who has a grievance against Mr. Dunham, has organized a rival company to be known as the West Springfield & Agawam Company and published notice that he would apply for a franchise. The route planned for this road is from the old toll bridge in West Springfield, down Bridge street and out to the Agawam river, over which a bridge is to be built, and thence to Agawam, Feeding Hills and Mittineague by branch lines. The capital stock of the West Springfield & Agawam Company is $100,000.

Houston, Tex.—A fifty-year franchise for an electric railroad in this city has been granted to J. C. Ward, E. L. Bacon and their associates, all of whom are stockholders in the electric light company.

Hudson, N. Y.—An extension of the Hudson street railway to Philmont is contemplated. Engineers and contractors have been looking over the route.

Lewiston, Me.—The railroad commissioners have issued a certificate to the Lewiston, Brunswick & Bath Street Railway Company for the operation of that section of the road between Lewiston and Topsham, a distance of 18.75 miles. This completes the certificates that will have to be issued to the road, as the whole of it is now in operation. The entire road comprises a distance of a little over 45 miles.

Montreal, Can.—One of the car sheds of the Montreal Street Railway Company was destroyed by fire on the 16th inst. The damage amounts to about $150,000. There were inside of the shed 68 cars, 28 closed cars and 20 that were under way. There were some thirty motors in the shed valued at $50,000. They were all destroyed. Seven sweepers were completely destroyed. Only six cars in the shed were saved. The property destroyed was insured for $90,000.

Newport, R. I.—The Boston "Gazette" states that the gross earnings of the Newport & Fall River Street Railway Company, which is largely owned by Boston people, from June 19—when it commenced operations—to August 31, were $27,462, and the net $14,327. The interest requirements for a full year are $12,000, so that already in 73 days the road has earned its fixed charges and $2,327 besides.

Oswego, N. Y.—There is now under consideration the project of a trolley line from Syracuse to this city as an extension of the Lakeside road from Baldwinsville, Phoenix, Fulton and Oswego Falls. Receiver Tidman of the Lake Ontario and Riverside road of Oswego will bring plans for the proposed extension before the Lakeside directors in a few days.

Pine Bluff, Ark.—Work has been begun on the new electric car line which is to be established here, in connection with an electric light plant, by Indiana capitalists.

Portland, Me.—There is talk here of building an electric railway around Long Island in Casco Bay. The island is capable of being easily transformed into an attractive summer resort and a street railway is considered an essential feature of such a scheme.

Richmond, Ind.—Dayton (O.) capitalists have been looking over three proposed routes for an electric line between Eaton, O., and this city. Dr. J. E. Lowe, who is connected with the Dayton and Eaton line, now in successful operation, is at the head of the new enterprise. He estimates the cost at $400,000, and says the line will be as good as any in America. The survey of the chosen route will begin immediately.

San Francisco.—The Market Street Railway Company intends to convert the steam railway running from California street to the Cliff into an electric line. It is stated that the new electric line south of the park has proved a success beyond the anticipations of the directors. The old dummy line was for years operated at a loss. The new line has not only paid the cost of operation but has paid interest on the cost of construction as well.

Wabash, Ind.—The owners of the South Bend system are reported to have purchased the Indiana Electric Company's line connecting Elkhart with Goshen. The new owners, it is said, will build a trolley line from South Bend to Goshen this fall.

Watertown, N. Y.—The Black River Traction Company is negotiating for a water privilege on the Black river in this city with the purpose of erecting a power plant for the production of electricity for use in the operation of its railway system.

Wichita, Kan.—It turns out that the money was behind the bond for $10,000 tendered by H. B. Church as a guarantee that he would build and equip a first-class street railway and electric light plant in this city. On the evening of the 13th inst., Joseph O. Burdett of Boston appeared in the council chamber, and was loudly cheered as he walked up to the city clerk's table, in front of Mayor Ross, and counted out ten thousand dollars in crisp new bills, good and lawful money of the United States, and said he was ready to pay it over the moment the franchise asked for by Mr. Church was passed and approved by the mayor. A franchise was at once drawn up by the city attorney, passed by the council and signed by the mayor, and ten one thousand dollar bills were immediately handed over to the cashier of the Fourth National Bank, in which the city funds are kept, who, guarded by the assistant chief of police and the city treasurer, took it to the bank. In the franchise Mr. Church's company is named the Wichita Railway, Light & Power Company.

Woonsocket, R. I.—The "Call" states that work will be begun in a few months on the new electric road that is to connect Attleboro with Boston by the way of Franklin and South Framingham. The new line will connect with the Inter-State Consolidated road at Plainville and extend through Wrentham by Lake Pearl along the Creek road to Franklin, and will be 20 miles in length. This will be the connecting link between Providence and Boston in that direction. The promoters include George W. Wiggin, Joseph G. Ray, Edgar K. Ray, Edward H. Rathburn, Charles W. Shippee, William S. Reed, William H. Tyler and O. T. Doe. The new system will be known as the Milford, Attleboro & Woonsocket Street Railway Company.

Wrentham, Mass.—The selectmen have granted the Milford, Attleboro & Worcester Street Railway Company the right to operate a street railway through Wrentham.

LIGHTING.

Birmingham, Ala.—A new electric light plant will be set up at Ensley City to furnish light to the steel mill and the furnaces. Work will be begun on the plant on the 1st of November. The estimated cost is $20,000.

Bridgeport, Conn.—The electric light plant at Pleasure Beach was destroyed by fire on the 19th inst. The loss is estimated at between $7,000 and $8,000.

Cape May, N. J.—The court has appointed Joseph Q. Williams receiver for the Franklin Electric Light Company here, and by his orders the city is again illuminated.

Camden, N. J.—The lighting committee of the city council has instructed the city clerk to communicate with municipalities operating their own electric lighting plants and ascertain the cost of building and maintaining them. The committee, however, also decided to advertise for bids for lighting the city with electricity for one, three and five years. The present contract expires next June.

Crescent City, Fla.—Two applications have been made to the town council for an electric lighting franchise. The applicants were C. H. Cash of Miller & Cash, city water works, and W. J. Pierpont of the Pierpont Manufacturing Company. The applications were laid over for one month for consideration.

Greensboro, N. C.—The Industrial & Immigration Society of this city has passed a resolution in which the board of aldermen is urged not to enter into any contract for lighting the streets "until every possible effort shall have been made to secure an electric system that shall furnish to the city: street lights; incandescent lights for stores, offices and residences; convenient electric power for small manufacturing enterprises, and a street car system." The aldermen have taken up the matter for consideration.

Hudson, N. Y.—Charles J. Cooper of Brooklyn, who recently purchased the Hudson street railway, has just closed negotiations by which he also becomes sole owner of the plant and franchise of the Hudson Electric Light & Power Company.

Kansas City, Mo.—Electricians have begun the work of stringing wires for the carnival illuminations which will be this year more beautiful and elaborate than ever. Among the displays will be electric fountains and arches, and it is intended to make the whole city a blaze of light. The carnival week begins October 2.

Manheim, Pa.—F. E. Bailey & Co., for the Manheim Electric Light, Heat & Power Company, have secured the franchise for lighting the streets of Mt. Joy. The distance from Manheim to Mt. Joy is about seven miles and the line connecting the two places will be erected at once. Water and steam power have been and will continue to be used on an enlarged scale in the plant at Manheim, which, with the improvements now in course of construction, will make it an important electric light station. Incandescent lamps will be used in the streets of Mt. Joy.

New Orleans.—The "Picayune" of the 18th inst. says: "The ordinance permitting Cohn & Ber to build and operate an electric plant for the manufacture of light and power has been promulgated, and this places three franchises of this character in the hands of local people. If all three are established there will be active competition for the lighting of the city provided that the franchise committee holds up the ordinance to advertise the lighting of the city, now in their hands."

Orangeburg, S. C.—An election is called for the 27th inst. to vote on an issue of $40,000 worth of bonds for the erection of waterworks and an electric light plant.

Philadelphia.—Frank M. Riter, director of the Department of Public Safety, advertises for proposals for furnishing electric arc lights for the city for the year 1899, bids to be received until October 4. All bids must be made upon printed blanks to be furnished by the department, and accompanied by a certified check to the order of the city treasurer for $5,000.

Pittsburg, Pa.—On account of the unparalleled electrical illumination which is to be provided to do honor to the Knights Templars who are to meet in conclave here during the week beginning October 8, a host

of electrical experts are expected in the city. It is estimated now that fully 400,000 lamps will be used, and half of these will be colored. One of the great centers of illumination will be the ball room, which is capacious enough to hold 25,000 people and will be lighted with all the splendor that artistic disposition of arc and incandescent lamps is capable of dispensing.

Pratt City, Ala.—Paschal G. Shook and associates have been granted a franchise for an electric light plant in this city.

Somerville, Tenn.—An electric light plant to cost $10,000 is to be established here.

Rawlins, Wyo.—The electric light plant of this place has been purchased by J. A. Rendel, who will resign his position in the First National Bank and devote his entire time to the management of the electric light business.

Wooster, Ia.—An election is to be held here on November 8 to get the public vote on the question of issuing bonds for an electric light plant.

MANUFACTURING, ETC.

Kalamazoo, Mich.—A factory for the manufacture of trolley wheels under a new patent is to be established here immediately. The company has a capital of $10,000.

St. Louis.—A car company in this city has received an order from Japan for 250 street cars to cost $300,000 and to be delivered within ninety days.

Washington, D. C.—The Navy Department, through the Bureau of Yards and Docks, is inviting sealed proposals until October 15, 1898, for installing an electric light and power plant at the United States Naval Station, Puget Sound, Bremerton, Washington. The appropriation for the work is $9,800. Prospective bidders desiring specifications and details of the work can obtain the same upon application to the chief of the Bureau of Yards and Docks, Washington, D. C., or to the commandant of the Naval Station at Bremerton, Washington.

TRANSMISSION PLANTS.

Columbia, Pa.—There is a fair prospect now of the immediate repairing of the dam on the Susquehanna river near Wrightsville for the Martic Water & Power Company as the bids are all in. On October 10 proposals will be received for 24 turbine water wheels and necessary shafting. It was the company's first intention to build its power house on the rocks below the dam, but it is now said that the house will be erected on Mud Island, about half a mile from the dam, and fed by a tail race. The latter will be constructed on the York county side. The company will furnish electricity for lighting and power to towns and manufactories in the neighborhood.

Lowville, N. Y.—The Wetmore Electric Company is at present securing the right of way from Belfort to Lowville by air line, instead of following the highway, and in this way will shorten the distance about 3 miles, making the total distance a little over 11 miles. The company will commence setting poles and stringing wires in a few days. A large number of men are at work on the raceway at Belfort. Provision is being made at the Beaver river falls for placing three dynamos of 230 HP. each. The plant will be operated continuously day and night, so that electricity can be used for lighting or power at any time.

Montpelier, Vt.—The Bolton Falls water power privilege has been secured by the Consolidated Electric Lighting & Power Company, who have awarded a contract to W. H. Ward & Co., of Lowell, Mass., for the building of a dam and power house at that place. Generators of an improved pattern will be put in, and it is the intention of the company to furnish electricity for heating, lighting and power to this city and to Barre, Waterbury and Stowe. The company expect to have about 2,000 horse-power for sale beyond what they need for their own uses.

COMPANY MATTERS.

Boston.—The Continental Construction Company, whose incorporation has just been completed, has secured a handsome suite of offices at 170 Summer street. The "Traveller" says of the company: "The management is in the hands of parties with large experience both in machinery and in the building and equipment of electric railways and electric light and power stations, which two lines of electrical application will constitute the main outlets for the business push of the concern. Ample capital has been secured, and the charter of the corporation is broad enough to permit the handling of almost any enterprise that offers a fair show for profit. The company now controls the franchises of several electric railways which are to be built in the near future, work on some of which will be well advanced this autumn. The manager announces that there is business enough in sight to absorb all its energy for perhaps a year to come. It thus enters the field full-fledged and with every prospect of a successful career."

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—In the inquest into the death of John McGraw, who was electrocuted, about two weeks ago, while working on the electric wires of the Albany Railway, it was decided by the coroner's jury that deceased had met his death through his own neglect. The fact that he wore no rubber gloves was an important point in the opinion of the jurors.

Burlington, Vt.—The mayor has signed the resolution giving use of the river road to the Burlington Traction Company.

Fonda, N. Y.—The Cayadutta Generating Company have purchased the electric plant of the Streeter Brothers and state that they will now furnish light cheaper than ever. They have fine water power at Berryville for the purpose, and will soon be in active operation.

PERSONAL AND MISCELLANEA.

A. L. Gillette, recently electrician of the Terre Haute Electric Railway Company, has been appointed superintendent of the electrical department of the Marinette (Wis.) Light & Power Company.

A London dispatch states that the first section of the electric railway to the summit of Jungfrau, the famous mountain of the Swiss Alps, has been opened as far as the Aasiger glacier, and it is expected the road will be finished by the year 1904.

City Electrical Engineer Jacques Morgan has planned an electrical steam fountain, situated on the roof of a prominent building in Kansas City, Mo., for throwing many colored jets of steam high into the air during Carnival week. This feature is an entirely new one, and it is said that a much more beautiful effect can be obtained with steam than with water, which has generally been used in displays of this kind.

The San Francisco "Examiner" of the 15th inst. says: "A new motor car was operated yesterday on the California street cable railway route. The inventor of the new motor is John Ryder of this city. The motive power is a secret composition that resembles gasoline. The car is intended to be operated only where grades are slight. The inventor says he can run a car at a cost of $1 a day. The invention on this first trial appeared to be successful."

A letter from Manila, received at San Francisco, tells of the brave conduct of E. E. Kelly of the Signal Corps during the engagements before the Philippine capital. In the heat of the conflict he carried a wire a mile and a half right into the Spanish intrenchments while the bullets fell around him like hail. Two comrades fell alongside of him, one fatally wounded. For his bravery he was made first sergeant. Gen. Merritt has sent his name to President McKinley, recommending recognition of his "gallant and meritorious conduct during the capture of Manila," and it is expected that he will at least get a Congressional medal.

A new signaling device to aid ships at sea to converse with one another at long distances has been invented by John W. Haywood of St. John's, N. F. The new machine is an adaptation of the magic lantern principle. The lantern is a powerful one and is supplied with a battery on stenciled plates containing the letters of the alphabet. These plates are connected by a series of levers with a keyboard, much the same as in a typewriter. The keys are marked with the letters and pivoted in such a way that when one presses down on one of the keys the corresponding slide is drawn up in front of the lens, and the letter is thus thrown out vastly enlarged. The lantern makes it possible to throw a series of letters in dazzling light upon a sail, a house or upon the clouds, so that they may be seen readily for a distance of several miles. The keyboard attachment enables the operator to project these letters so quickly that a long signal may be spelled out almost as quickly as it could be written on a typewriter. The scheme may be used either in the merchant marine or on warships or from lighthouses. It admits of a cipher being used for secret messages and is adaptable to any language. The device has already been tried with gratifying success on a warship.

RECENT COMPANY ELECTIONS.

Cayadutta Electric Railroad Company, Gloversville, N. Y.—Directors: J. H. Decker, Harwood Dudley, Thos. E. Ricketts, J. Ledlie Hees, George M. Place, A. J. Zimmer, Gustav Levor, Samuel H. Shotwell, Robert T. McKeever, John G. Ferres, G. W. Judson, Z. B. Whitney and E. C. Shotwell.

Denver Consolidated Tramway Company, Denver, Col. —President, Rodney Curtis; secretary, W. G. Evans; superintendent, C. K. Durbin; directors: the officers and George E. Ross-Lewin, Samuel H. Elbert, Frank Trumbull, James H. Blood, W. N. Byers, C. F. Musgrove, S. M. Perry, Thomas Keeley, W. F. McClelland and N. O. Jelliff.

Mount Holly Electric Light Company, Mt. Holly, N. J.—President, Amos Gibbs; secretary and treasurer, Samuel A. Atkinson; directors: Amos Gibbs, Benjamin F. Lee, James L. Jamison, Robert L. Nixon, Dr. Parsons, Joseph C. Cowgill, Samuel Atkinson and Edward D. Stokes.

Worcester Electric Light Company, Worcester, Mass.—President, Thomas M. Rogers; clerk and treasurer, Herbert H. Fairbanks; superintendent, William H. Coughlin; directors: Thomas M. Rogers, Stephen Salisbury, Loring Coes, Gen. A. B. R. Sprague, N. S. Liscomb, Theodore C. Bates and Gen. Josiah Pickett.

COMMERCIAL PARAGRAPHS.

The Ludewig-Thurber Manufacturing Company, 565 Old avenue, Pittsburg, Pa., beg to announce that having removed to more commodious quarters and having their shop more fully equipped with modern machinery they are better prepared to handle all classes of electrical repair work than heretofore. This well known concern is giving special attention to armature and field winding, refilling of commutators, etc., and is now ready to quote prices consistent with first-class work. The firm also buys and sells motors, generators and other apparatus of similar nature.

The attention of our readers is directed to the advertisement of Thomas A. Edison, Jr., which appears elsewhere in this issue. The Edison Junior "Improved" Incandescent Lamps are now so well known that a detailed description of their many advantages and good points would be superfluous. As will be recalled, this make of lamp attracted considerable attention and drew forth many favorable comments by its brilliancy at the Electrical Exposition in May last. These lamps are manufactured at Shelby, Ohio, while the general offices and salesrooms are located at 27 William street, New York City. With a view to giving one an idea of how extensively these lamps are being used, it is only necessary to state that Mr. Edison, Jr., has found it advisable to establish branch offices at 60 State street, Boston, at St. Paul, Minn., at Los Angeles, Cal., at Norfolk, Va., at Austin, Tex., and at Santiago de Cuba.

The Electric Appliance Company, Chicago, have just printed a special catalogue devoted exclusively to Anchor switches. This catalogue is fully up to date, embodying all the recent improvements that have been made in snap switches. The catalogue is supplied with a special discount sheet to the trade and altogether makes a valuable little reference book on switches. It can be had for the asking.

"Helps in Brazing."

The Dixon Crucible Company of Jersey City, N. J., has published a little pamphlet with this heading. It treats incidentally of brazing graphite, the application of which to bicycle tubes prevents the adherence of the spelter and so effects a saving in labor by making unnecessary the filing which is otherwise needful. The pamphlet, however, especially treats of the process of brazing by the dipping method, or "liquid brazing," as it is called. The brazing crucible is described, together with instruction and caution in regard to its use. Instructions are given how to build and set the necessary furnace, time required for brazing, etc., etc.

In regard to the economy of liquid brazing as against the old-time fire brazing, the following is quoted from a well-known bicycle manufacturer:

"We have been using the process of liquid brazing all this season, but at first found some difficulty in keeping the spelter at the proper temperature. We built several furnaces before we succeeded in getting one entirely successful. The one we have now in operation enables us to do as much work with one man and a boy as we were able to do before with five to seven men, and the results are much more satisfactory. We figure that we effect a saving of $20 per day every day we run the new furnace. Besides requiring fewer workmen, we use only about 125 pounds of hard coal in a day's run, which is quite a contrast to the expense we were under with the old gas furnace, when our gas bills amounted to $250 per month. With the new process one man and a boy can turn out seventy-five machines in a run of seven hours."

The pamphlet is of interest to all bicycle manufacturers and others who do brazing. It is sent free of charge.

INCORPORATIONS.

The Lancaster & Jefferson Electric Light Company, Lancaster, N. H. Capital stock, $36,000.

The City of Lincoln Gas Company, Chicago—to furnish gas and electricity to the city of Lincoln, Ill. Capital stock, $10,000.

The Dowd Electrical Company, Albany, N. Y. Capital stock, $100,000. Incorporators: Henry Fitch, Pepperell, Mass., and others.

The Empire Heating & Lighting Company, St. Louis. Capital stock, $5,000, all paid. Incorporators: S. L. Cohen, John Costello and J. C. Robertson.

The Electric Connecting Railway Company, St. Louis—to operate a street railway in St. Louis and Jefferson Counties. Capital stock, $2,000. Incorporators: M. T. Chestnut, John H. Bobring and James D. Houseman, Jr.

The Standard Light & Heat Company, Philadelphia (incorporated in West Virginia). Capital stock subscribed $100, with privilege of increasing to $1,000,000. Incorporators: R. Miles Robinson, William L. Teter, E. O. Wharton and Henry Robinson, Philadelphia; Joseph W. Irwin, Govanstown, Md.

The Safety Third Rail Electric Company, New York—to supply electricity and deal in goods, etc., pertaining to electricity. Capital stock, $1,000,000. Directors: Emerson McMillin, Emerson McMillin, Jr., W. F. Douthitt, C. T. Scoville, R. H. Beach, William M. Keepers, David F. Halsted, John McLeod Murphy and Louis Steckler, of New York City.

The Potosi & Rio Verde Railway Company, New York City—to construct a steam or electric road 66 miles long in the State of San Luis Potosi, Mexico. Directors: Robert S. Towne, George Foster Peabody, Edward M. Shepard, A. Foster Higgins, Charles J. Nourse, Jr., Herbert H. Dean, Samuel H. Ordway and Francis N. Holbrook, of New York City, and Donald O. Brown, of San Luis Potosi.

ELECTRICAL PATENT RECORD.

Letters Patent Issued September 20, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

610,891. Electric-Railway-Car Truck. George J. Capewell, Hartford, Conn. Filed June 14, 1898.

610,927. Trolley. Olof W. Swanson, Tacoma, Wash. Filed Sept. 18, 1897.

610,982. Electric Locomotive. William S. G. Baker, Baltimore, Md. Filed Nov. 24, 1894.

610,999. Electric Heater. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, same place. Filed March 18, 1895.

611,000. Electric Coupling. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, same place. Filed Jan. 9, 1896.

611,001. Electric-Heating System. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company, same place. Filed July 6, 1896.

611,053. Electric-Railway Construction. William Chapman and Percy W. Davies, Pittsburg, Pa. Filed Nov. 23, 1897.

610,915. Fender or Guard for Cars. Peter J. Poelman, New Orleans, La., assignor of one-half to Chris Jacob, same place. Filed May 18, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

610,898. Electric-Arc Lamp. Max Harris, New York City, assignor to the Manhattan General Construction Company of New York. Filed Oct. 27, 1897

611,162. Electric-Arc Lamp. Frederic S. Worsley, London, England, assignor to the British Blahnik Arc Light Company, Limited, same place. Filed March 15, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

610,887. Automatic Circuit-Breaking Switch. William F. Bossert and William D. Pomeroy, Utica, N. Y., assignors to the Bossert Electric Construction Company, same place. Filed July 12, 1897.

610,895. Controller for Electric Motors. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 2, 1898.

610,899. Electric Meter, Caryl D. Haskins, Newton, Mass., assignor to the General Electric Company of New York. Filed June 24, 1898.

610,903. Circuit-Breaker for Three-Wire Systems. Edward M. Hewlett, Schenectady, N.Y., assignor to the General Electric Company of New York. Filed Sept. 7, 1897.

610,904. Safety Device for Dynamo-Electric Machines. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed April 4, 1898.

610,908. Electric Brake. John B. Linn, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Jan. 7, 1898.

611,006. Combined Generator and Steam-Engine. Marey L. Whitfield, Memphis, Tenn., assignor to the American Dynamo Engine & Motor Lamp Company of Tennessee. Filed Nov. 16, 1897.

611,087. Contact Finger for Controllers or Electric Switches. Thorsten von Zweigbergk, Cleveland, O., assignor to the Walker Company, same place. Filed Feb. 23, 1898.

611,088. Governing, Reversing and Braking Controller. Thorsten von Zweigbergk, Cleveland, O, assignor to the Walker Company, same place. Filed Feb. 23, 1898.

611,089. Method of and Means for Controlling and Cutting Out Electric Motors. Thorsten von Zweigbergk, Cleveland, O., assignor to the Walker Company, same place. Filed April 29, 1898.

611,090. Controller. Thorsten von Zweigbergk, Cleveland, O., assignor to the Walker Company, same place. Filed April 29, 1898.

611,151. System of Electrical Distribution. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed Oct. 22, 1897.

611,205. Circuit-Interrupting Device. Daniel M. Moore, Newark, N. J., assignor to the Moore Electrical Company, New York City. Filed July 3, 1897.

611,215. Electric Controller. Samuel Harris, Twinsburg, O., assignor to the Steel Motor Company of Ohio. Filed May 2, 1898.

BATTERIES.

611,012. Electric Battery. Victor Jeanty, Paris, France. Filed Oct. 21, 1897.

611,175 Galvanic Element. Robert Krayn and Carl Koenig, Berlin, Germany; said Krayn assignor to said Koenig. Filed June 19, 1897.

MISCELLANEOUS.

610,907. Apparatus for Electroplating Articles in Bulk. Georg Langbein, Leipsic, Germany. Filed Jan. 22, 1898.

610,928. Electrostatic Measuring Instrument. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed March 27, 1897.

611,100. Electroplating Apparatus. Hermann B. Boissier, New York City. Filed Jan. 14, 1898.

611,142. Electric Furnace. Riccardo Pignotti, Ferdinando Lori, Scipione Regnoli, Marco Besso and Maffeo Pantaleoni, Rome, Italy. Filed June 27, 1896.

611,148. Apparatus for Electrically Coating Wire. William S. Rawson, London, England. Filed Dec. 24, 1897.

611,185. Rheostat. Charles H. Richardson and Lewis McMakin, Jr., Philadelphia, Pa., assignors to the S. S. White Dental Manufacturing Company, same place. Filed Feb. 3, 1898.

DESIGNS.

29,366, 29,367, 29,368, 29,369. Electric Lamps. George R. MacIntire, New York City, assignor of one-half to Elliott P. Gleason, same place. Filed March 18, 1898.

29,370, 29,371. Lightning-Arrester. Herbert C. Wirt, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 29, 1898.

29,372. Field-Magnet Frame. Edward D. Priest, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 26, 1898.

29,373. Casing for Dynamo-Electric Machines. Walter S. Moody, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 8, 1898.

29,374. Motor and Fan Case. Herbert A. Balcome, Boston, Mass. Filed Aug. 18, 1898.

29,375. Frame for Generating Sets. Fritz Handel, Boston, Mass. Filed Aug. 18, 1898.

TELEPHONE AND TELEGRAPH.

The telephone situation in Washington, D. C., is rather tantalizing to users. By an act of Congress it is "unlawful for any person or any telephone company doing business in Washington to charge or receive more than $50 per annum for the use of a telephone on a separate wire; $40 for a telephone there not being more than two on a wire; $30 for each telephone there being not more than three on a wire, and $25 for each telephone there being four or more on the same wire." The telephone company, holding that the law is unconstitutional, refused to comply with its provisions when patrons endeavored to take advantage of it, and the result has been a series of suits in which the local judges have invariably decided against the company, but the latter has determined to carry the matter to a higher court, and any injunctions issued against it are in a measure rendered void. Those using telephones are required to give surety to secure the company against loss in the event the Supreme Court shall decide the act unconstitutional, and even under the restrictions of a restraining order already issued by Justice Hagner, a new subscriber would be able to procure the service of a telephone for $50, but by using its privilege of appeal the telephone company can avoid furnishing the service unless the proposed patron pays its established rate of $125 for the use of an instrument within a distance of a mile of the central office, and the graduated scale of prices adopted by the company and in force long before Congress enacted any legislation upon the subject.

A press dispatch from Minneapolis, Minn., dated September 20, says: "Negotiations which have been pending some time were closed to-day whereby the Northwestern Telephone Exchange Company, the Western Electric system, the Western Electric Telephone Company, the Minnesota Mutual Telephone & Telegraph Company, and all of the dependent and allied companies, operating in between 500 and 600 towns, will pool issues and operate their lines in direct connection. This will make it possible to reach about 8,000 miles from Minneapolis by wire, and enable the city to talk with all parts of Iowa, Nebraska, Missouri, Kansas, Illinois, and in fact as far as electricity will carry the voice."

The Topeka, Kan., *Journal* says there is a telephone war on in Atchison. Some time ago a company was organized and secured a franchise to give Atchison a second company. Poles are now being set, and the new company will be ready for business within 60 days, and will furnish business telephones at $2 a month and residence telephones at $1 a month, a considerable reduction from the prices the old company has been charging. Last week the old company—the Missouri & Kansas—put four solicitors at work making contracts for residence telephones at 75 cents a month and business telephones at $1.50 per month.

The Baltimore & Ohio Railroad Company is about to experiment in using the telephone for long distance communication. Work will begin in a few days on the construction of two new copper telegraph lines between Baltimore and Pittsburg, 340 miles, and they will be so arranged that when the necessity arises they will be available for telephonic communication. One of the wires will be extended as far as Newark for telegraphic use. A new line has also been constructed between Columbus and Cincinnati. It will take 800 miles of copper wire, weighing 166 pounds to the mile, to complete the work.

The Albemarle Telephone Company at Charlottesville, Va., has elected the following officers: President, J. Edwin Wood; vice-president, James F. Hardin; directors: John B. Moon, J. M. Robinson, Phil Leterman, J. B. Andrews, M. Kaufman, W. J. Tyson and S. C. Chancellor. The president reports 416 'phones now in operation, and that the system has been extended to many important points twenty-five miles distant from the city. Arrangements are being perfected by which the line will in the near future be extended to Staunton, Lynchburg, Orange Court House and other cities.

Sartaro Oi of the Department of Telegraph and T. S. Horiye of the Department of Industries, of Japan, were in Chicago a few days ago inspecting the telegraph and telephone systems. "Our visit is of a semi-official nature," said Mr. Oi, "and relates to the proposed extension of our telegraphic communication system. We have 50,000 miles of telegraph wires in the empire, and nearly that amount of telephone wires, but we propose to extend this system so that it will include every settlement of any size in the country."

A correspondent of the St. Paul *Dispatch* at Aberdeen, S. D., states that the management of the Dakota Central Telephone Company are very much disappointed over the Bell Company having absorbed the Minnesota Central system. It was expected that a rate of 75 cents for a five-minute talk could be arranged between the two companies, but the Bell Company has raised the rate to $2.25, out of which the Dakota line gets 25 cents.

The Volunteer Signal Corps.

General Greely has issued an order relieving from duty, preparatory to muster out, the Volunteer Signal Corps. He says he cannot permit the men to return to private life without acknowledging their "loyal, efficient and valuable services to the nation." In reciting the services rendered by the corps in Santiago and Porto Rico he says:

"In the Santiago campaign you were the first of the army to arrive, as you were the last to leave. Destroying within range of Spanish guns the submarine cables that gave the enemy daily information of inestimable value, when the occupation of Santiago was ordered you repaired cables with such celerity that you opened communication between the United States marine camp at Caimanera (Guantanamo) and New York City on June 21, the day prior to the landing of the Fifth Army Corps off Santiago. Owing to your efforts, the American army in Cuba has not been isolated telegraphically a single day.

"In the Cuban campaign you arranged, maintained and operated a system of cable and land lines—partly commercial, partly war cables, partly flying telegraph lines and partly telephone lines—that enabled messages to pass in twenty minutes from the Executive Mansion in Washington to the headquarters of the army before Santiago, and which offered direct and immediate communication between the Secretary of War in his office and the Signal Corps men in the advanced rifle pits on the right, the left and in the center of our intrenched army, within 400 yards of the enemy. When the city fell your lines followed immediately army headquarters as it moved therein.

"No one will ever know the difficulties—physical and moral, climatic and service—under which you labored in Cuba. Heat and thirst, hunger and fatigue—these present sufferings, with impending disease and death, you endured and faced uncomplainingly with the rest of the army; but these conditions never prevented the prompt, cheerful and efficient discharge of the important duties devolving unremittingly day and night upon the Signal Corps.

"In Porto Rico you were with the advance, participating as scouts and skirmishers in the capture and occupation of towns. From the beginning to the end of the campaign you kept each important command in telegraphic or telephonic communication, both with the corps commanders and also with the base of operations.

"The Signal Corps has filled neither the guard house nor the hospital. Serving in the field in Cuba, in Porto Rico, in the Philippines, and in home garrisons at Tampa, Chickamauga, Camp Alger, Jacksonville and Montauk, yet your total aggregate of over thirteen hundred has lost by disease in camp and field to date only five—officers and men included."

General Manager H. J. Hanford of the Kinloch Telephone Company, St. Louis, says the service of the company will be put in operation October 1. The testing of the connections of the switchboard are about complete. The telephone boxes of the company have been distributed and it has between 4,000 and 5,000 subscribers.

The stockholders of the Tidewater Telephone Company at a meeting at Gloucester Court House, Va., on the 19th, re-elected the old officers and added J. A. Bristow to the board of directors. The superintendent's report for the year showed that 5 per cent. had been earned upon the stock. The company has 77 stations.

The Mississippi Valley Telephone Company has been granted the right at St. Paul, Minn., to use all the public alleys in the district bounded by University, Selby, Cleveland and Herschel avenues for its pole lines. The work on the conduit lines of the company is well under way.

The Inter-State Telephone Company will erect a line between Winston and Greensboro, N. C., as soon as its construction force completes the new plant the company is putting in at Raleigh.

The American Telephone & Telegraph Company of New York has filed at Jefferson City, Mo., evidences of incorporation in Missouri, the capital to be used in that Stat being $10,000.

The stockholders of the Bell Telephone Company of Philadelphia on the 20th inst. voted unanimously to increase the capital stock from $2,000,000 to $3,000,000.

The Commercial Cable Company of New York has filed with the Secretary of State at Albany a certificate of increase of capital from $100,000 to $500,000.

The Inter-State Telephone & Telegraph Company has been granted a franchise to construct and operate an exchange at Salem, Va.

The telephone office at Tucson, Ariz., was destroyed by fire on the 18th inst.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12½c.; Lake, 12¼@12⅜c.; casting, 11⅞@12c.

The Lynn & Boston Street Railway Company has declared a semi-annual dividend of 4 per cent., payable September 30.

The Fourth Street & Arsenal Street Railway of St. Louis was sold under foreclosure on the 20th inst. to John H. Overall for $191,000.

The Westinghouse Electric & Manufacturing Company has declared a quarterly dividend of 1¾ per cent. on the preferred stock, payable October 1.

The Boston Electric Light Company has declared a regular quarterly dividend of 1½ per cent., payable October 15 to stock of record September 30.

Application has been made to list on the New York Stock Exchange Westinghouse Electric & Manufacturing Company $575,000 additional assenting stock.

The dividend of 50 cents per share on the stock of the Pennsylvania Manufacturing, Light & Power Company, Philadelphia, is payable October 15 to stockholders of record September 30.

George J. Gould since his return from Europe, judging from statements attributed to him, is more than ever impressed with the proposed change from steam to electricity on the Manhattan Elevated.

The directors of the Big Consolidated Street Railway, Cleveland, O., have ordered a fourth quarterly dividend of 1 per cent. Each of the three previous quarterly dividends for the year 1898 was three-quarters of 1 per cent.

The directors of the Louisville City Railway Company have declared payable the semi-annual dividend of 2½ per cent. on the preferred stock of the company, but owing to tax suits against the company by the city of Louisville the dividend on the common stock was passed.

The directors of the American Bell Telephone Company have declared the regular quarterly dividend of 3 per cent., payable October 15. The dividend makes 10½ per cent. declared so far this year, three regular quarterly dividends of 3 per cent. and 1½ per cent. extra dividend in June, payable July 15.

At the annual meeting of the Union Traction Company at Philadelphia on the 21st inst., the old board of directors, including J. Lowber Welsh, who was persuaded to reconsider his announced intention to retire, was re-elected without opposition. John B. Parsons has been elected president of the company and George Widener vice-president.

The plans for using electricity as the motive power on the Brooklyn Elevated Railroad are now so far advanced that a resolution providing for its use will be introduced at a meeting of the directors to-morrow (Thursday). The divisions of the road on which the electrical equipment will first be placed will be the Fifth and Lexington Avenue lines.

A report has been current during the week that the Third Avenue Railroad Company, New York, in changing their equipment to electricity will make provision for electric lighting. They recognize the economy of combining power and lighting interests in a great plant such as they intend to erect, on account of the strain from the two services coming at different periods of the day.

The City Passenger Railway Company of Baltimore offers its new stock of $1,000,000—issued by the company to pay for recent extensions and improvements—to such existing stockholders as desire to avail themselves of the privilege, at the rate of forty shares at $50 a share for each 100 shares of old stock held. The par value is $25 a share. This privilege expires on September 30.

The Edison Electric Illuminating Company of New York reports gross earnings for August of $202,516, an increase of $32,169 as compared with the same month of last year, and net $67,692, an increase of $1,470. For the eight months ending August 31 the gross earnings were $1,949,639, an increase of $379,072 as compared with the corresponding period of last year, and net $819,452, an increase of $122,481.

The Chicago "Times-Herald" of the 20th inst. says: "Announcement was made yesterday on competent authority that the City Railway Company has rid itself of a dangerous rival by absorbing the South Side Elevated Railway. It is stated that the surface road assumes $750,000 outstanding bonds and guarantees 4 per cent. on the $10,328,800 capital stock of the elevated. The transfer will take place, it is further said, January 1."

An official of the General Electric Company, who is credited with authority to speak, says: "The only relation that the General Electric Company sustains to the reported Walker-Westinghouse arrangement is that if the purchase has been made by the Westinghouse Company, the General Electric Company has the full right, by reason of its previous agreement with the Westinghouse Company, to use all the patents and devices of the Walker Company."

It is stated in the Boston "News Bureau" that "no plan has been definitely formulated as yet by the directors of the General Electric Company for the payment to preferred stockholders of accumulated dividends amounting to $35 per share. It may be said, however, that these dividends will be paid out of earnings subsequent to August 17, on which date the stockholders voted to reduce the capital stock, thereby wiping out the previously existing deficit of $12,000,000. About the middle of October it is expected that a definite plan for their payment will be prepared and issued to shareholders."

The United Electric Securities Company, Boston, under its 39th call retired $10,000 of its collateral 5 per cent. bonds of the fifth series at 100.8, leaving $432,000 of this issue still outstanding; $5,000 of the eighth series were retired at 102.4, leaving $256,000 outstanding; $24,000 of the ninth series were retired at 102.42, leaving $302,000 outstanding. The company invites proposals for the sale to it of so many of its collateral trust 5 per cent. bonds of the eighth series as can be purchased with $188,588. Proposals will be received at the office of the company until 12 o'clock M. October 5.

The New York "News Bureau" states that "President Albert L. Johnson of the Nassau Electric Railroad Company of Brooklyn confirms the report that R. T. Wilson had parted with his holdings to Edward H. Harriman, who probably represents ex-Governor Flower of the Brooklyn Rapid Transit system. Mr. Johnson also stated that if the object is to consolidate or combine the Nassau and Transit trolley railroads, by means of a traffic agreement or a lease, he would not be opposed to it if the scheme was a good one and not opposed to his interests." Mr. P. H. Flynn is understood to have softened in his opposition to the deal, but no definite arrangement has as yet been reached.

The Boston "Commercial Bulletin" of Saturday last says: "The sharp advances in General Electric from time to time have not been explained except by stories mostly invented to explain them. Thursday's advance was based on the report that George Gould's return from Europe would be followed by the adoption of electric traction on the New York elevated lines. Sooner or later the Manhattan will have to come to this, but it is making progress slowly. It was a little curious that in the face of this news, used as a 'bull argument' on General Electric, Manhattan stock should have suddenly broken nearly four points on Thursday, with sales of nearly 20,000 shares. One favorite Wall Street story has it that Pierpont Morgan has got control of the elevated lines. Of course this is nonsense. The only 'point' likely to turn out true is, that if the antequated management of the concern does not mend its ways and do something to retain its custom dividends will presently have to be suspended."

EDITORIAL NOTES.

Electricity for the Operation of Gun Turrets on Men-of-War.

Now that three new first-class battle ships are about to be added to the United States Navy, the question as to whether it is advisable to have the gun turrets of these vessels operated by electricity or in the manner now generally in vogue, by steam, would seem an all-important one. Although much valuable information was gathered during the recent war as to construction and best type of ships for naval use, unfortunately, owing to a combination of circumstances, there was but little opportunity of judging of the real merit of electricity as a motive power for heavy work. So far as electricity was used, that is to say, for operating searchlights, signaling, ventilating, etc., it proved eminently satisfactory. To the best of our knowledge the Brooklyn alone of all the fleet utilized the electric current in the operation of a gun turret, and as no adverse report was sent in it is to be presumed that everything worked smoothly. There would certainly seem to be many advantages in utilizing electricity to operate the gun turrets and winches on a man-of-war. In the first place, a modern fighting ship has to be provided with anywhere from six to eight generating sets in order to obtain sufficient current for operating the signal bells, signal lamps, incandescent lamps and searchlights. Thus, with very little more power added, numerous steam rams and donkey engines now required in the handling of the ammunition and turrets could be done away with entirely. With the present system no less than three bulky engines are required in a turret not over fifteen feet in diameter, whereas were electricity adopted one small motor could in all probability be made to do the work. A method of accomplishing this was recently described in the New York *Sun* as follows:

"The exact manner in which the electric current would be applied to the turret gear has not yet been determined. Many schemes have been devised, all of them practical according to the ideas of the officers in the Construction Department. One plan provides for a large motor to be situated in one of the ducts leading to the turret. This motor would furnish the necessary power for the operation of the turret itself, as well as the two lifts needed to bring the projectile into position. By this system the rams would be dispensed with altogether, as the projectile would be placed upon a little motor car in the magazine, carried by it to the lift, raising it to the level of the floor of the turret, and thence to the lift communicating with the breech of the gun. The place of the myriad steampipes, donkey engines, greasy hydraulic cylinders and complicated levers would be occupied by two small electric cables, while the officer in command by throwing a switch on the board placed in the firing tower in the turret would have under his own control the working of the entire system."

The doing away with bulky steam pipes is decidedly an advantage, as the temperature would be reduced as well as the danger. There would certainly seem to be a far greater chance of a pipe's being perforated by the bursting of a shell than of a wire being broken, as the former would naturally offer a far greater surface than the latter and could moreover not be so easily repaired. The main electrical conductors could, for that matter, be protected by running them in heavy insulated cables under the deck. Of course there is always a chance of a breakdown occurring in the dynamo room, but with eight or ten generating sets so arranged that any set may be switched into any circuit little trouble need be apprehended from such a cause. As it is the aim of the United States that these three battle ships when completed, which however will probably not be for three years, shall be the finest and most modern warships afloat, provision should be made for operating the gun turrets and other heavy machinery by electricity, otherwise we shall awake to find that Germany, which is fast adopting electricity in its navy, has not been so conservative, and that our newest warships are in reality not up to date.

* * *

Lower Rates for Electric Current.

From all accounts the New York gas companies will be obliged to look after their laurels, and may not have such a monopoly in the illuminating line as they have been enjoying for past years. A strong competitor has entered the field against them in the Edison Electric Illuminating Company—not that the latter concern has not been in the field some time, but until now the prices charged for electric light were such as to make it almost a luxury. A few days ago the Edison Company sent out a circular addressed to its customers stating that owing to the adoption of new apparatus, combined with the use of cheaper fuel, it is in a position to offer electric current at much lower rates than heretofore. The prospectus says:

"The Edison Company, in accord with its declared policy of reducing prices and encouraging the more general consumption of electric current, particularly for long-hour use, and in continuation of the reductions announced in its circular letter of October 28, 1897, will replace its present schedules for both incandescent and arc lighting by the reduced rates

scheduled below, on bills due after October 15, 1898 (including partially September lighting).

"These rates give customers the benefit of the fact that electricity for long-hour use can be produced and sold cheaper than any rival illuminant. A consumer using one lamp 8 hours a day requires an investment in station apparatus and street conductors only one-eighth that required by a consumer using 8 lamps one hour a day though the consumption for one day is the same in both cases. Although operating costs, for coal and other supplies, varying almost directly with the amount of electricity produced, do not show a like saving, yet the long-hour user can be supplied at a much lower rate per hour than the short-hour user, reaching half or less proportion of the one-hour price.

"For retail use, 20 cents per kilowatt hour (equivalent to 1 cent per 16 candle power 50 watt incandescent lamp hour, or 10 cents per standard arc lamp hour) for first hour's average daily use of the total lamp equivalent connected; 15 cents (¾ cent or 7½ cents) for the second hour; 10 cents (½ cent or 5 cents) for the third and fourth hours; and 5 cents (¼ cent or 2½ cents) for all use above four hours.

"For wholesale use, with a guarantee of 2,000 kilowatt hours consumption each month and two hours average daily use of installation, 10 cents per kilowatt hour for the first four hours average daily use and 5 cents for all use above four hours; or, at the option of the consumer, the present wholesale or kilowatt rate of 10, 9, 8 and 7 cents per kilowatt hour for 2, 4, 6 and 8 hours average daily use, with reductions for quantity, etc.

"These prices cover both incandescent and arc lighting and include renewal of incandescent lamps (not exceeding one 16 CP. lamp for each 20 kilowatt hours), and the carbons and trimmings for arc lamps, but not first supply of lamps. The company, however, in accordance with general practice, waives for the present the last condition and continues, until further notice, the first supply of incandescent lamps."

It is further announced that, provided the present rates prove as successful as the officers of the company are led to believe they will, a still further reduction for long-hour use may be made to ¾ cent per 16 CP. incandescent lamp hour. This reduction in the price of electric light should without question greatly increase the number of private consumers, especially now that electric light will cost no more than gas for long hour use. The latter illuminant is used by people of moderate means throughout the city almost exclusively, owing to the fact that electricity has heretofore been considered too expensive. But probably the principal aim of the Edison Company in thus reducing its rates is to create a demand for electricity in cooking and heating, and thus secure if possible a day load for its central stations. A considerable amount of cooking is at present being done in this city by gas, and if electricity can be furnished equally as cheap there would seem to be no reason why the electric current should not gradually be adopted for this purpose. In fact the circular, referring to this subject, says: "To encourage cooking, heating, etc., by electricity, household apparatus for cooking, heating and ventilating will until further notice be excluded in reckoning installation." This we presume means that a person using electricity for cooking or heating purposes would be charged for it the same as though the current was utilized for lighting, which, together with the current used for lighting, would make long-hour use, and consequently be charged for at a lower rate. By adopting these measures the Edison Company may possibly solve a vexed question and secure a day load, or possibly this reduction in the price of electricity may be the means of bringing about what legislative action has repeatedly failed to do, namely, a material reduction in the price of gas in this city.

Electricity in Belgium. Belgium is apparently appreciating the advantages of electricity for lighting and power purposes in spite of strenuous opposition to its introduction by the owners of gas works in various cities throughout that country. From an official report furnished by the Bureau of Foreign Commerce it is learned that the first trial of the complete electric installation for the lighting of the railway station known as the Gare du Midi in Brussels was but recently made and proved entirely satisfactory. The Government was in fact so well pleased that it has recently signed a contract for a similar installation in the South Depot at Ghent.

When the city authorities of Brussels, but a few years ago, proposed the question of lighting public places, such as railway stations, parks, etc., by electricity, and of supplying electricity to subscribers the same as gas, a great cry was raised and protestations made against any such innovation, insisting that it would ruin the gas works and bankrupt the communal exchequer. What little foundation there actually was for any such apprehension, however, may be gathered from recent statistics which go to show that during the past year not only has the use of electricity increased but also that the profit from the sale of gas is considerably in excess of that of previous years. This fact, strange as it may seem, is by no means unusual, and although seemingly contrary to what might have been expected, is simply another proof that the introduction of electricity into a community does not necessarily mean bankruptcy to the local gas company.

The most important installation now being made in Brussels is in the king's palace. When the work is finally completed there will be 7,500 lamps in all, of which a large number will be of five candle-power, located in the many chandeliers illuminating the ball and reception rooms.

In the city system there are now about 47,391 lamps, a large number of which are of sixteen candle power, averaging 117 lamps per hundred running meters of street. Included in the above number are 770 arc lamps. There are twenty eight electric motors in the system, varying from one-tenth to ten horse power and aggregating a total of 150 horse-power.

The maximum sale of electric current during 1897 was 8,763 amperes, corresponding to that necessary to operate about 17,530 lamps of 16 candle power functioning simultaneously, or about 37 per cent. of all the lamps at present installed.

In view of the increasing use of electricity in Belgium, there would seem to be an excellent opportunity for the introduction of American electrical apparatus, although difficulty might be experienced in competing successfully with machinery manufactured in Germany owing to the proximity of the latter country.

Under the Searchlight.

Notes and Comments on Various Topics.

THE Worcester (Mass.) *Telegram* says experts are beginning to believe that the danger to life and property from thunder-storms in suburban localities is increased by the increasing use of electricity in the cities. Now, there is a great deal of suburb around electric New York, much of it in New Jersey, but we have not heard of any remarkable increase in damage or fatality due to thunder-storms in late years, and even "Jersey lightning," whose reputation as a killer dates from away back, has grown if anything a little less nocuous since the product of the dynamo came into general use.

* * *

THE motor car movement has, says the London *Financial Times*, enriched the English language with some new and particularly ugly words, but it would appear that we must not complain, for the Flemish Academy at Antwerp has been discussing the correct equivalent of the French "automobile," and, among other suggestions, has had to deal with that of "Snelpaardelooszonderspoorwegpetroolrijtuig." The expression appears to require a good deal of sub-editing before the citizens of Antwerp can hope to save time by hailing a vehicle of this description.

* * *

Wanted Something Fresh.

The following interesting little anecdote is from *Lightning*, London: "The retired provision merchant had a few thousands for investment, and his nephew, who traveled in most things electrical, from lampholders and storage cells to dynamos, motors, and meters—and in a motor car—had his eye on those same thousands. So he took his venerable relative round to an accumulator shop, and explained in highly technical language the advantages of the particular type of cell in which he was interested, and especially how the depreciation had been brought down to an insignificant figure. He was great at technicalities, and from their constant use had come to think himself a consulting electrical engineer. But the old man was not impressed. 'How long do these things last, then?' he asked. 'For years; haven't I just been explaining it to you?' 'Then they won't do for me,' replied the ex-provision merchant. 'What I like to deal in are the things you start to sell fresh every morning.' Even that did not discourage the bagman. He promptly took his victim round to a factory for arc lamp carbons, where the desired deal came off."

* * *

THE St. Louis *Chronicle* of September 28 says: "Dr. Heber Robart thinks he has found a cure for asthma by the use of electricity. Gertrude Pence, the 11-year-old daughter of Daniel Pence, a prominent citizen of Springfield, Mo., was cured. It was the first experiment along lines never before attempted by a surgeon in this country. The electricity was applied in spray form through wooden electrodes."

* * *

ELECTRICITY is not all of life, and it is a relief to sometimes direct the beams of our searchlight beyond its confines and bring to view some of those things that are lying around outside. In the San Francisco *Examiner* of a recent date we find the following conversion of our national hymn, "My Country, 'Tis of Thee," into Spanish by one Don Tomas de Nunan. Although it is evident that Don Nunan, in setting out to accomplish the translation, mounted a bucking broncho instead of the ordinary Pegasus, it is quite as evident that he got there all the same:

Mi patria, de ti,
Cuba y Puerto Ri—
co libre son.

Comprendo Tio Sam
Un hombre fuerte am,
Although tenemos ham—
bre muy mal.

Las Filipinas, si!
El Senor Dewey, he—
Caramba! Ay de mi!
Has taken them.

Our great buques de guer—
Ra! Gallant ships that were!
Porque did we imper—
il them near Schley?

Re-cu-er-da el Maine!
We faced their flag in vain—
They're raising el in Spain!
Raising hob son!

Mi patria! ha, ni
Las islas en el sea
Ni ironclads have we—
Ni nada left.

* * *

THE *Electrical Engineer* of London says: "The other day we happened to be on board ship with a

number of well-known engineers as well as a general cargo of passengers. One of the general cargo let everyone around him know that he was an electrical engineer. We have in our time met many electrical engineers, but had never previously seen to our knowledge this particular specimen, nor do we ever wish to see him again. Some of the engineers aboard were closely connected with electrical undertakings, and naturally questions were asked—and answered by the specimen. Now practical men always harp on the question of cost, so it was news to some of us to hear the specimen emphatically assert and reiterate again and again that the total cost of generation per unit could not be much less than 6d. Under exceptional circumstances it might be reduced to 4d. The moral is this—do not talk with strangers on subjects you know very little about. As one gentleman remarked, 'I knew a good deal more than he imagined, and so could not believe anything he said.' The best of it was, the specimen quoted chapter and verse for his statements, and the singularity of his proofs was that they always concerned installations by 'Lord This' and 'Sir Somebody' that." Unfortunately for the good of the electrical industry, this type of so-called engineer is frequently to be met with in other countries besides England.

"MONEY IN RAILROAD BUILDING."

Under the above caption the article subjoined appeared in the Brooklyn (N.Y.) *Eagle* of September 29. It is suggestive:

"Albert N. Johnson, president of the Nassau Electric Railroad Company, has said in discussing the prospective consolidation of all the railroads in this borough that he will withdraw from active connection with the consolidated company if the present plans should be carried out. He can make more money building railroads or developing those in bad condition. Mr. Johnson knows whereof he speaks. People who have followed the history of the Nassau system and of the other railroad systems in this borough have no doubt of the correctness of his views. Let us look at some reported facts: The original Nassau system was bonded for $4,000,000 and stock to the amount of $6,000,000 was issued. The bonds were supposed to cover all the cost of construction, including the cost of obtaining the franchises and consents of property owners. The stock was issued as bonus to the men who took the bonds, and in payment of commissions for raising the money. Patrick H. Flynn obtained one-half of the $4,000,000 of bonds, the other half went to the Wilsons, who were the capitalists of the concern, and to the Johnsons, who supplied the railroad experience. The Wilsons received about one-half of the capital stock and the other half was divided between the Johnsons and Flynn. This was about five years ago. The Nassau system later absorbed the Atlantic Avenue system and there was a recapitalization of the consolidated roads to the amount of $15,000,000. Of this the Wilsons are supposed to have held about $10,000,000, and the Johnsons and Flynn the remainder, or about $5,000,000. The Wilsons have sold their holdings of stock to men supposed to be interested in the Brooklyn Heights system on a basis of about 80 per cent. of its par value. The Johnsons are said to be asking par for their holdings. They will probably get somewhere near that figure.

"Now assuming that the original bonds of the Nassau system represented actual cash expended, there is a profit in about five years on an investment of $4,000,000 of the respectable amount of at least $5,000,000. This does not take into account the money made on the recapitalization of the Atlantic Avenue Company after consolidation. It simply includes the original Nassau road. The stock, while not representing cash invested, does represent what the promoters of the railroad think that the business is worth. In other words the stock is the capitalization of the value of the franchises. Each share represents a proportionate share of the profits of the road. If there are no profits above operating expenses then the stock is worth little save for speculative purposes. In view of all these facts no one will doubt Mr. Johnson's statement that there is more money in developing than in operating railroads."

Meeting of the American Institute of Electrical Engineers.

The American Institute of Electrical Engineers held its 127th meeting at its headquarters, 12 West 31st street, New York, on Wednesday evening, September 28. The meeting was called to order about 8 o'clock with Dr. Kennelly in the chair. After the usual routine of business had been gone through with, a paper entitled "The Photometry of the Enclosed Alternating Arc," by Charles P. Matthews, W. H. Thompson and J. E. Hilbish was read. An interesting discussion followed in which Louis B. Marks, W. H. Freedman, Captain John Millis of the Lighthouse Board, and Dr. Kennelly took part. About fifty members were present. The meeting adjourned about 10 o'clock. At the meeting of the council on September 28 the following were elected into the Institute:

Frederick William Carter, Lecturer in Electrical Technology City and Guilds of London Institute, London, Eng.

Walter H. Coleman, Superintendent and Treasurer Andover Electric Co., Andover, Mass.

Henry L. Doherty, General Manager and Engineer Madison Gas & Electric Co., Madison, Wis.

George W. Frank, Jr., Secretary, Treasurer and General Manager Kearney Electric Co., Kearney, Neb.

R. H. Mansfield, Jr., Electrical Engineer and General Manager Ward Leonard Electric Co., Bronxville, N. Y.

Kempster B. Miller, Chief Electrician Western Telephone Construction Co., Chicago, Ill.

Gilbert Rosenbusch, Engineer Sprague Electric Co., South Orange, N. J.

John West Thompson, Superintendent Cia. de Luz'y Fuerza Motriz Electrica, Guadelajara, Mexico.

Henri Tripier, Counsel and Technical Engineer of the Compagnie des Transports Electriques del Exposition, Paris, France.

Herbert A. Wagner, General Superintendent Missouri-Edison Electric Co., and also with Wagner Electric Mfg. Co., St. Louis, Mo.

William Henry Williams, Professor of Mechanical and Electrical Engineering Montana State College, Bozeman, Mont.

A New Company With a Big Capital.

The New York Gas & Electric Light, Heat and Power Company, with a capital of $25,000,000, was incorporated on the 3d inst. at Albany. Its stated objects are to manufacture and supply gas and electricity for light, heat and power purposes in the territory of Greater New York. The corporation is to have the right to purchase and hold the stocks and bonds of any foreign or domestic corporations and exchange therefor its own stocks and bonds. The organization tax of $31,250 was paid to the State Treasurer by a check of the Central Trust Company drawn on the Bank of America. The directors are Henry J. Hemmens, Frank D. Allen, Frederick L. Allen, J. Frank Yawger, Louis M. King, Charles N. Flint and Nathaniel W. Smith of New York City.

Consolidation Completed.

The consolidation of the Edison Electric Illuminating Company of Brooklyn with the Kings County Electric Light & Power Company was completed on Monday last. The Kings County Company becomes the owner of the Edison stock, and by virtue of the ownership of this stock will own the stock of the Citizens' Lighting Company and the Municipal Lighting Company of Brooklyn. This purchase gives the Kings County Company substantially all the electric light business in the borough of Brooklyn.

CALCIUM CARBIDE WORKS AT INGLETON.*

BY F. J. A. MATTHEWS.

The advantages claimed during the past two or three years for the new illuminant, acetylene gas, added to the number of patents applied for for generators by persons living in Lancashire, Yorkshire, and other populous centers, and the consequent advertisement of the new gas, have directed the attention of many engaged in the production of lime to the subject of the manufacture of calcium carbide. Amongst others Mr. James Carter, of Blackburn, well known in the district as a coal merchant and lime burner, and who possesses extensive quarries and kilns at Clitheroe, was attracted by the commercial prospects of its manufacture on a large scale in the heart of the industrial region where it would be used, and the saving of its heavy rate of freight. Accordingly, he approached Messrs. Ashton, Frost & Co. (Limited), engineers, of Blackburn, with the view of having experiments carried out in their works. With this suggestion Mr. Park, the general manager, readily agreed, and I, as chief electrician, was instructed to build an experimental furnace, and for several successive weeks trials were made under varying conditions. This furnace was simply a crude brick contrivance lined with ganister, with vertical carbons, and completely open at the top. As the only dynamo we could spare for any lengthy trials gave as its utmost output 65 volts 400 amperes, and the open furnace permitted a vast quantity of valuable heat to escape, we found the cost of manufacture to be heavy, and the carbide to be unequal, that is, we got lumps of very pure carbide exceedingly rich in gas, but mingled with it masses of unfused, and partially fused, lime and coke. However, sufficient data were obtained to show that not only were the samples of lime and coke used of the best for this purpose, but also, with modern appliances and a current of not less than 1,500 to 2,000 amperes, the carbide could be produced at a price which would leave a fair margin of profit, especially if, as in the case under consideration, water power were available, even allowing for the fall in market price which was inevitable with the opening of many new factories.

At the same time it was considered advisable, as ample money could be found for the project, to proceed only on the most modern and efficient lines; about this time M. Raoul Pictet published his two pamphlets—"Le Carbite Nouveaux Procédés pour sa Fabrication" and "L'Acétylène, son Passé, son Présent, son Avènir." After careful consideration of M. Pictet's patents and system with those of others, it was finally decided to secure a license to build one of his furnaces, and eventually terms were arranged, and a convenient site secured a Ingleton.

Before, however, describing the actual plant at Ingleton it would be well, as these are the first furnaces erected under M. Pictet's patents in the United Kingdom, to give a brief sketch of the principle upon which M. Pictet has founded his system. The chemical formula for calcium carbide is CaC, and to obtain this (outside purely laboratory methods) lime (CaO) and coke (C), each in a fine powder, are mixed together approximately in the proportion of 65 per cent. of lime to 35 per cent. of coke, and raised to a high temperature, roughly about 6,000° F.; usually this has been done at one operation by means of the electric arc in a suitable furnace. The chemical changes which take place in the furnace, while the mass is subjected to this tremendous heat, consist in the greater part in the oxygen being driven off the calcium and uniting with a certain percentage of the carbon to form the monoxide and dioxide of carbon, chiefly the former, while at the

* From the *Electrician*, London.

same time the calcium combines with the carbon to form the required calcium carbide. The combination of the oxygen with the carbon, and of the calcium with the carbon, are both of the nature of combustion and evolve heat in so combining, but this heat cannot be used directly in the furnace, owing to the high temperature required in order to drive off the oxygen from the lime, and also because a very high temperature is necessary to enable calcium and carbon to unite. The various purposes for which thermal units are required may be tabulated thus:

(1) To raise the lime to the temperature of liquefaction.

(2) To supply the latent heat of liquefaction.

(3) To provide the heat necessary to disassociate the lime.

(4) To provide the heat requisite for the combination of calcium and carbon.

M. Pictet points out in his pamphlet that in order to procure an intense cold, say for the liquefaction of air, no one would think of proceeding by one single operation, but by several progressive steps; so also to obtain an excessively high temperature, recourse should be had to the same method of advancing by successive means, hence his first furnace was built in a series of zones. Starting at the top we have: (1) An ordinary blast furnace, coke being used for fuel, where obtains a temperature of 3,600° F. (2) An oxy-hydrogen blow-pipe zone, where obtains a temperature of 4,300° F. (3) An electric arc zone where obtains a temperature of 5,600° F. to 6,000° F. By this method the electric arc only comes to the assistance when all other cheaper means of securing a high temperature have done their utmost, and as the furnace is fed from the top, and the mass gradually sinks down and comes under the influence of each zone successively, the cost of manufacture is greatly reduced. In actual practice the second or blow-pipe zone might be omitted, as the benefits derived from it are not commensurate with its cost. In his later furnaces, such as those at Ingleton, built under a more recent patent, several alterations are made, and while the same broad principle is maintained of proceeding by degrees, the waste gases of the furnace and the heat obtained by the combination of the calcium and the oxygen with the carbon are made to do the work of the two first zones described above.

At Ingleton the plant consists of two furnaces, one 120 kilowatt dynamo, driven from a waterwheel 30 ft. in diameter, with a 12 ft. bay, assisted in time of drouth by a pair of compound horizontal condensing engines. The dynamo possesses several new features. Its normal output is 2,000 amperes, at 60 volts, with 425 revolutions per minute, but it had been designed to run without sparking even when temporarily overloaded to an extent of 50 per cent. It is of the makers' four-pole type, with cast-steel magnets and yoke; the armature is of the slotted drum type, with helical duplex winding, the armature inductors being of Crompton's patent compressed stranded cable, the end connections being carried on a special prolongation of the spider. There are 68 sections to the commutator and 68 inductors to each part of the duplex winding. In order to prevent sparking owing to the armature reactions when the machine is grossly overloaded, overcoming the magnetic flux of the field, a slot $1\frac{1}{4}$ in. in width and the full width of the magnet is cut through each magnet and pole, and continued through the yoke at right angles to the lamination of the armature. Exhaustive tests were also made in order to obtain the exact bore and correct rounding of the polar shoes, to secure as far as possible absolute fixity of lead, with the result that the machine runs without alteration of lead with variations of from 1,000 to 1,500 amperes, this being in dynamos for furnace work a most essential feature, as the molten mass in the furnace is constantly causing the external resistance of the circuit to vary, and the current fluctuated in one particular run from 800 to 2,500 amperes—17 times in 10 minutes. The compounding turns consist of a sheath of polished copper on each field. The brushes are 16 in number, in four rows of four each, the rocker being operated by a worm gear and hand-wheel. The armature complete weighs 30 cwt., and the whole machine 7 tons. The designs and drawings of this machine were checked by and the tests carried out under the superintendence of Mr. Albion T. Snell, the consulting engineer.

The furnaces are two in number, but as each furnace requires 2,000 amperes for economical working, the second is intended, until the generating plant is increased, for use in case of breakdown to the first. The furnaces now consist of an inner part or furnace proper, roughly 2 ft. square by 3 ft. high; this part is built of bauxite bricks, with an outer casing of fireclay bricks. At the front there is a partition between the two, in which before the furnace is started a fire is kindled. The carbons are 6 in. square, the negative one being inclined at an angle of 30 deg., while the positive carbon is fed forward by a screw motion which gives a horizontal travel. Where each carbon enters the furnace wall it is surrounded by a sheet-iron water jacket. A second water jacket is also fixed round the part of the copper carbon holder where the cable is sweated in. A good water circulation is maintained from cisterns placed in the room above, while, in order to prevent short-circuiting, the water jackets on each side are supplied from separate cisterns, which are supported on wooden stands, and the overflow from the jackets is made to drop from a good height into a common waste pipe. Each pipe, both supply and waste, is provided with a stop-cock to regulate the flow, and no pipe is of continuous metal, but for 6 in. of its length consists of india-rubber.

Each furnace is built on foundations of ordinary brick, provision being made for a track to be run underneath, into which the molten carbide falls. Along with the carbide a large quantity of carbon monoxide escapes from the furnace, and a flue at the back of this opening, assisted by a good draught, leads this round the furnace between the two linings to the top of the furnace where the hot gases are utilized. From the top of the furnace proper an iron tube, inclined at an angle of 25 deg., leads to the upper chamber. This tube is perforated along its upper part to permit of the escape of the hot gases, and is enclosed in a firebrick flue. Where the flue reaches the floor of the top room it is bent at right angles to its former direction, but the inner tube is carried straight on through the flue-slide into the room, and there closed by a suitable door, while the flue proper is continued into the shaft of the chimney. Through this tube the furnace is fed with the mixture of carbon and lime, while along the flue travels the carbon monoxide from the furnace together with the other hot gases, the fire, referred to above, in the front of the furnace being made to create a draught in the first instance. These hot gases, greatly assisted by the heat of combination of both the calcium and the oxygen with the carbon, heat the constituent materials as they pass down the tube, so that they enter the furnace proper already at a high temperature. The lime and coke are compressed into briquettes about 2 in. square, in order not to choke the arc, and allow a freer passage for the escape of the hot gases.

The main switchboard consists of an enamelled slate board mounted with a 12 in. dial voltmeter reaching to 75 volts, an ampere-meter with 12-in. dial reading to 2,500 amperes, and graduated to read in 20 amperes, double pole fuses, and a shunt resistance and multiple switch. Each furnace is further controlled by a single-pole multiple lever switch. The main cable consists of such a number of strands of 19s. B.W.G. copper wire as give three square inches of solid copper and is compressed to a rectangle $2\frac{1}{2}$ in. by 2 in.; this cable is run along the floor on insulators and where it rises to the carbons is suspended by suitable swinging hangers from the roof. The gearing is of a very strong and substantial nature, the dynamo being driven by a 45-in. pulley adapted for six ropes $1\frac{1}{2}$ in. in diameter; the intermediate drive with a lower belt speed consists of ten ropes $1\frac{1}{2}$ in. in diameter, while the bearings are automatically lubricated by means of rings dipping into an oil reservoir.

The plant has now been working for the past week or two with most satisfactory results, and the carbide tested by an independent expert yields an average of 5 cubic feet to the pound.

POSSIBLE FUTURE MOTIVE POWER FOR TRAMWAYS.*

BY W. H. BOOTH.

There can be no doubt that the next great industrial movement in Great Britain will be in the direction of electrical traction. Everything has pointed that way for some time. Something we want, and have wanted for years, and we are unable to define just what this something is. A year or two ago the light railway fever broke out, but this was but a symptom of a deeper seated complaint, which will find its cure in the establishment of electrical traction, not in the fitful manner to which we are so far accustomed, but in a downright business manner. For the present, doubtless, electrical tramways will be worked from ordinary power stations deriving their power from the combustion of coal. But it is questionable if this wasteful system will continue; we say wasteful, because there is running to waste in Great Britain a very Niagara of power, of which, so far, the only utilization has been—to continue a hydraulic simile—by means of a small float wheel anchored in the rapid current, no real use of the fall being made. The waste referred to is that which goes on week in, week out, every day of twenty-four hours, Sunday included, from year end to year end, and continuously as Niagara itself, in the shape of gases discharged from the blast furnaces of the iron manufacturing districts. Roughly some ten or twelve million tons of fuel are consumed annually in the making of pig iron in Great Britain, and it has been estimated that if the gas could be properly utilized it would produce continuously nearly two and a half million horse-power. It is perfectly obvious that, granted the possibility of using the gas, there need be no fear for the future of electrical tramways, or indeed any other form of electrical utilization.

All waste powers have been found to call for very considerable expenditure in bringing them to a position for being utilized. Water power, for example, requires such heavy outlays on canals, dams, pipe lines and tunnels, that it is very seriously doubted whether it can compete with steam power. It can well compete in southern California, where coal is imported from England and is very costly, and there is no frost and therefore no need for the expense of a stand-by steam plant, but in the Eastern States of America, with their severe winters and the necessity of steam plant as a stand by, the saving by water power is very problematical.

Turn now to the case of the blast furnace and note the contrast. In the first place the blast furnace is already in existence and fuel is already being consumed therein. Compared with a steam power plant, we have already got the equivalent for the boiler and we have the fuel to use up as a waste product. Compared with a water power plant we have got everything except the turbine. We have all the head works and pipes. All that remains to be done is to put down gas engines and dynamos and manufacture electricity for transmission to any reasonable radius round every blast furnace. To

* From *Railway World*, London.

Mr. B. H. Thwaite is due the credit of seeing the waste and supplying the remedy. He recognized that the gas produced by the blast furnace was almost identical with that produced by the gas producer, and at once realized the possibility of using it in gas engines. The first plant put down for the purpose was at the works of the Glasgow Steel & Iron Company, at Wishaw, near Glasgow, and being called in to make a test of this plant I am able to give a few figures from the results I found. First, however, attention may be drawn to the accompanying two analyses, the one of ordinary producer gas, or *gaz-pauvre*, as it is termed in France, where a good deal has been done in the way of using it for power purposes, and another from a blast furnace and taken for me by Mr. Galbraith, the manager of the Wishaw works.

TABLE I.

	Blast furnaces at Wishaw.	Average of four typical gas producers.	Average of four typical blast furnaces.
Carbonic Oxide CO......	24.75	27.61	30.76
Hydrogen H..................	2.33	3.59	0.50
Marsh Gas CH_4..........	0.75	1.21	0.80
Nitrogen N..................	66.42	61.10	53.60
Carbonic Acid CO_2.....	5.75	6.49	14.44
	100.00	100.00	100.10
Per cent. combustible..	27.83	32.41	32.06

It will be noticed that approximately one-third of each gas is combustible, the remainder being diluents and of course chiefly nitrogen. Such diluted gases are not perhaps very inflammable, but they do burn fairly well under steam boilers, though they are very inefficient as steam producers, owing to their lack of heat radiating power and also to the low temperature of the flame they produce. When Mr. Thwaite first proposed to use these waste gases, he was of course laughed at, but this did not deter him. Having command of a gas producer, he made a gas exactly resembling blast furnace gas, and proved its capability in a gas engine of several horse-power driving a dynamo and producing light. The modern gas engine with its compressive cycle can use very poor gas; the compression gets over all difficulties of this nature, and for hours the engine at Wishaw never made a "miss fire," nor could I learn from anyone that he had seen or heard it do so. The demonstration plant laid down to test the issue consists of a gas engine of 20 horse-power, which draws its gas through a holder or gasometer supplied by a fan or blower which draws air from the large gas pipe returning the gas from the residuals recovery plant, coal being the fuel used in these as in other Scotch furnaces, and a residuals plant being therefore necessary. The whole plant is thus exceedingly simple. The gas engine drives a dynamo, which supplies current at 100 volts to the following lamps—10 arc lamps placed in five groups of two in series, one incandescent lamp of 50 candle-power, 11 of 32 candle-power and 68 of 16 candle-power, used variously to light the furnaces, the residuals plant and the offices. If the output of gas per ton of fuel used is known, the combustion of gas by the engine can be read off from the fall of the holder in a given time, the plant being so arranged that when a test is to be made the supply of gas to the holder can be stopped, and the gas from the blower returned by a bye-pass to the large gas main. The holder being 10 feet diameter is amply large to allow several minutes' run, and the voltmeter being kept steady and all lamps alight, the electrical horse-power is known, and the consumption of gas per horse-power is thus measurable. With gas produced at the rate of 180,000 cubic feet per ton, the consumption is as low as 105 cubic feet per hour per electrical horse-power. Somewhat poorer gas was being made at the time of my tests, and it probably measured 200,000 cubic feet per ton of coal consumed. The result was thus 140 cubic feet per electrical horse-power hour, which corresponds with a weight of 1.49 pounds of coal. Practically and briefly it may be stated that the first attempt to use blast furnace gas showed that after smelting the iron there could still be obtained from each $1\frac{1}{2}$ lbs. of coal one electrical horse-power—a better result than that obtained with the highest class of steam boilers and triple expansion engines, and there can be no doubt of the absolute success of the system, which has since been put into operation at the Frodingham Iron Works, in Lincolnshire, with equal success. For local duty the system will grow rapidly, but it would have been useless for other work but for the possibilities of electrical transmission. With this available, and power to transmit current 100 miles with a loss of only 30 per cent., there are opened up vast possibilities for traction work, factory driving, etc.

It is to traction work, however, that the new source of power will give the greatest impetus, and it is fitting that the movement promising so great an economy should be directed in the line of traction, that youngest of industries, and one requiring large powers. The certainty, uniformity and regularity of production of gas serve to render the blast furnace not merely ideal as a gas producer, but also ideal as a power generator. With it there can be nothing corresponding with shortness of steam, no risk of exploding boilers, no black smoke and no costly stoking. Blast furnaces are stoked by machinery of simple and cheaply worked description. They clear themselves of ash and clinker automatically on the opening of a tap hole. Economy in working is therefore secured. Moreover all the cost of working is covered by the prime product, pig iron: the gas is almost thrown away. There is yet another aspect of the case. The production of a furnace is increased by heating the air blast, and this is effected by burning some of the waste gases in a stove through which air is blown to the tuyeres. By abolishing the hot blast, or using it only at such moderate temperature as can be secured by using the temperature of production of the waste gas, not its heat of combustion, the iron produced can be of the superior cold blast variety, and will fetch a better price. That is to say, where gas can be sold at anything over cost price, it will matter less how much iron is produced per ton of fuel, a consideration now of importance, which at times leads managers anxious to economize to starve their pig. The main fact to notice is that after using fuel for producing iron there is still so much potentiality of energy remaining in its waste gas that when used in the gas engine it will produce more power than if the fuel were burned under steam boilers. This, of course, is due to the higher measure of efficiency of the gas engine as compared with the steam engine.

The following list of furnaces about a year ago in the various iron producing centers may be of interest:

District.	No. of furnaces.
Lancashire	16
Cumberland	17
Lincolnshire	19
Northamptonshire	8
Leicestershire	4
Derbyshire	18
South Yorkshire	12
West Riding	8
North Yorkshire	68
North Staffordshire and Shropshire	20
South Staffordshire	19
Worcestershire	4
South Durham	15
North Durham	11
Barrow	24
Flint	8
Glamorgan	8
Monmouth	19
Ayrshire	46
Lanark	44
Stirling	4

For a country using so much power as Great Britain there are no falls of water of any practical utility, unless we except the much debated Foyers and one or two others. Even if there were it is certain that the capital expenditure necessary to utilize them would exceed many times the expenditure necessary to use blast furnaces. Thus in South California, where several very important power installations have been constructed for transmitting water power about 30 miles, it appears that the initial cost is from £15 to £40 per horse-power, and there is no frost of any serious amount to deal with. Frost is almost fatal to the economical use of small water powers, but it is no difficulty in the case of gas power. A glance at the situation of iron producing centers on a map will show that within 30 miles of each there is a large field for power. Indeed at 30 miles radius many of the centers named would overlap in parts of their districts. The towns of the north, especially of the West Riding, are many of them badly connected by railways, and the manufacturing districts generally afford a huge field for electrical traction, which with so cheap a source of power ought to be a magnificent success. To talk of the decay of trade because of foreign competition is ridiculous in view of the great margins for economy which we possess in this country.

With electrical transmission, power can even now be carried 100 miles with say a loss of 30 per cent., and we may hope to secure better results when the magnitude of the undertakings permits a more liberal use of copper in the lines and higher voltages become practicable. The possibilities of power from blast furnaces are not realized yet in the minds even of engineers. The project is voted visionary by men to whom it is first broached. To such as these an inspection of the plant at Wishaw or at Frodingham would be more impressive than a year's persuasion. The details are so simple there is really nothing to understand; simply a gas propeller, a filter, a holder, and the engine and dynamos. Mr. Thwaite has been remarkably successful, perhaps, because in his demonstration plant he has everything made good and solid, and leaves nothing to chance as good enough for experiment. The plant inspected by the writer was well and carefully made, and its duty was visible in the illumination it afforded to the works. That the system will greatly forward the interests of electric transmission there can be very little doubt in the mind of anyone who will carefully consider the question with a map marked for population and for numbers of furnaces. According to the use made of the gases for hot blast and for working the blowing engines at a high or low pressure, so will the volume of gas for external purposes be more or less, but from 5 to 10 horse-power of continuous power may be expected from each ton of coal per week. Thus a small furnace of 500 tons fuel consumption would yield from 2,500 to 5,000 horse-power for continuous use. The importance of saving this power which now goes to waste cannot be over-estimated.

An Electrical Governor for Marine Engines.

Electric governors for marine engines are now being tried by Italian engineers. In one form recently invented mercury is depended on for communicating the effects of the rising of the propeller out of the water. There are two mercury vessels communicating with each other. When the ship rolls and the propeller rises the mercury runs from the one vessel to the other and cuts out a number of resistances connected to contact pins which pass into the space above the mercury contained in the vessel near the bow of the ship. This causes the current round a pair of electromagnets to increase, and the valve, being under the control of the electromagnet, closes gradually. When the bow rises the resistances are brought in again one by one and the circuit of another electromagnet is closed. This electromagnet also controls the valve and it is opened. When the keel is level no current goes through the electromagnets.

A New Provincial Electrical Association.

The Maritime Electrical Association held its first convention at Halifax, N. S., on the 28th ult. Among the papers read was one proposing to substitute electrical gong buoys for automatic and whistling buoys for purposes of navigation on Canadian coasts.

ON THE ELECTROLYTIC CORROSION OF WATER AND GAS PIPES BY THE RETURN CURRENTS OF ELECTRIC TRAMWAYS.*

BY DR. J. A. FLEMING, F. R. S.

The subject of pipe corrosion by the earth return electric currents of electric tramways has at various times attracted a considerable amount of attention. There is no need to refer to the experience gained in the early days of electric traction, chiefly in the United States, which impressed on engineers the necessity for proper and efficient bonding of the rails in those cases in which they act as the return circuit. The British Board of Trade regulations now in force, under which electric traction is at present conducted in the United Kingdom, prescribe precisely the conditions for the use of uninsulated metallic return circuits which are intended to prevent injurious electrolytic action on subterranean pipes. Among these rules an important one is the sixth regulation, in which the maximum permissible potential difference which may exist between a pipe and a portion of the neighboring rail return is stated. In the case of an overhead electric tramway working with an earth return in which the current returns to the generating station by the bonded rails assisted or not by return feeders, an electrical survey made, when cars are running, by measuring with a voltmeter the potential difference between the rails and any pipes buried in the earth in the neighborhood, generally will reveal certain districts over which the tram line rails are positive to the buried pipes in their neighborhood, that is, are at a higher potential. Certain other regions, usually near the generating station, will be discovered in which, on the other hand, the pipes are positive to the rails. The Board of Trade sixth regulation (ii) is as follows:

"If at any time and at any place a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in its vicinity, it shall always be possible to reverse the direction of any current indicated by interposing a battery of three Leclanche cells connected in series if the direction of the current is from the return to the pipe, or by interposing one Leclanche cell if the direction of the current is from the pipe to the return."

The above translated out of official language signifies that if the pipe is negative to the rail the potential difference shall not exceed 4.5 volts, and if the pipe is positive to the rail the potential difference shall not exceed 1.5 volts.

No matter what difference of potential may exist between a pipe and a neighboring rail it is well understood that electrolytic corrosion or damage can only ensue at any place under two conditions:

(1) The potential difference must create an electric current which leaves the pipe at that place; and (2) the conduction through the surrounding soil, or at least into it, which thus takes place must be electrolytic in character.

Hence, generally speaking, the danger areas are those in which the pipes are positive to the rails and where a resulting current flows out of the pipe into adjacent electrolyzable soil. Assuming then that the Board of Trade regulations are obeyed, the chief question of practical interest at present is to determine whether under normal conditions of working a potential difference of less than 1.5 volts between a pipe and the nearest part of an earth return, the pipe being positive to the return rail, is sufficient to cause an injurious action on the pipe by the production of electrolytic erosion. The matter is certainly largely determined by the nature and amount of the electrical conduction which can take place through ordinary soils, especially those which form the subsoil in towns and cities. Information has therefore been collected on this matter, and an experiment made in my laboratory with London clay taken from an opening in a London street made for laying down pipes, on December 14, 1897, gave the following results: The clay was packed into a dry, well-varnished wooden box, the interior measurements of which were: depth = 27.3 cms., width = 18.0 cms., length = 61 cms. Two clean sheet-iron plates were placed at the ends of the box, the dimensions of each plate being nearly as possible equal to the cross-sectional area of the column of clay. Wires were soldered to these plates. The resistance of the mass of clay, 61 cms. in length and 491.4 sq. cms. in cross section, was found to be 194 ohms when measured with proper precautions in the usual way with the Wheatstone bridge and two dry cells. Keeping this electromotive force applied the resistance soon rose to 277 and then to 283 ohms, indicating a progressive polarization of the plates and therefore an electrolytic conduction. A checking measurement was made also with the potentiometer and it was found that a potential difference of 100 volts, created between the plates, produced a current of 0.52 ampere through the column of clay, thus indicating a total resistance of 194.5 ohms. These consistent figures show that the resistance of the clay in its then condition of moisture was approximately 1,566 ohms per centimeter cube, or nearly 17 ohms per yard cube.

The resistance proved, as might be expected, to be immensely dependent on the state of the clay as regards moisture, greatly increasing as the clay dried up.

A mass of damp sand, moistened with water slightly salt, was found to have a resistance approximately of 1 ohm per yard cube.

Experiments by Dr. St. Lindeck* at the Reichsanstalt in Berlin in 1896 showed that cement blocks after immersion in water for 22 hours had a minimum electrical resistance of about 14 to 15 ohms per yard cube, but in their normal state a resistance of about 50 ohms per yard cube, and when especially dried by heating for 5½ hours to 100° C. a resistance of nearly 270 ohms per yard cube. The same investigator found that concrete (one part cement and five parts gravel) after being immersed for two hours in water had a minimum resistance of about 25 ohms per yard cube, but after being artificially dried for 4½ hours at 100° C. its resistance was of the order of 500,000 ohms per yard cube.

It has been frequently stated that concrete is a very bad conductor or fair insulator, and that rails laid on it are practically insulated, but the considerable decrease which takes place in the electrical resistance of materials such as clay, cement, concrete, sand and various soils, when impregnated with moisture, and the great increase which takes place when they are artificially dried indicates that the conduction through them in their normal condition is largely due to the presence of water, and must, in great part at least, be electrolytic in character.

In the average condition of moisture most of the materials forming the subsoil in town and city streets are not likely to differ much in conductivity from the sample of London clay, damp sand or cement, tested as above described, and will probably have a specific resistance between 15 and 30 ohms per yard cube. Although the above specific resistance is large compared with that of metals, being of the order of 1,000 million times that of copper, yet between extensive metallic surfaces buried in the soil, the actual total electrical resistance may be numerically very small. Between two 100 yard lengths of 6 in. clean iron pipe placed in clay ground a yard apart, and, say, 2 ft. deep, the actual measured resistance would in general be something of the order of 1 ohm. It is clear, therefore, that a continuously-applied voltage not exceeding 1.5 volts may cause the flow of very considerable quantities of electricity in the course of time between metallic surfaces of large area buried in the soil. Moreover, it is evident that a not inconsiderable portion, and perhaps the whole, of this flow, must be carried by electrolytic conduction. In any case, whatever may be the nature of the actual roadbed on which the rails rest the conduction out of the pipe will be in part electrolytic, if the pipe itself is in contact with ordinary soil. Under these circumstances the anode or pipe will be electrolytically attacked. Suppose that two iron plates or surfaces are placed in sand moistened with water, and having in it electrolyzable salts the acid radicles of which can attack iron. Let a current be made to flow from one plate to the other by creating a potential difference between them, then the passage of one ampere-hour out of the positive plate will remove or dissolve off from that plate 0.6968, or, say, 0.7 of a gramme of iron if the metal is removed in the ferric state, or 1.04 grammes if in the ferrous state. Since there are 453.59 grammes in one pound (avoirdupois), and since the specific gravity of iron is about 7.8, it is easy to see that one cubic inch of iron may be removed from the positive plate by the electrolytic passage out of it of some electric quantity between 127.7 and 182.5 ampere-hours. This is, very roughly speaking, *one ampere-week*. The iron so electrolytically removed may pass either into soluble iron salts, or may remain as an adherent layer of hydroxide. If chlorides, sulphates or nitrates are present in the soil, the iron may be removed partly as ferrous or ferric salts which may be diffused through the surrounding soil, or wholly or in part converted into insoluble and adherent ferric hydroxide by secondary reactions. It is important to know what is the least voltage which will effect this electrolytic corrosion. If the surrounding soil is of a nature to favor electrolysis, that is, if moisture and salts are present in it, a far less difference of potential than the maximum of 1½ volts permitted by the Board of Trade can produce rapid corrosion of an iron anode or plate. To illustrate this fact the following experiment was tried: Two plates of sheet iron were placed in a porcelain box filled with sand slightly moistened with salt water. The plates were kept at a difference of potential of 1 volt and at such a distance apart that a current of 1-20th of an ampere passed between them. At the end of ten days the positive plate was very much corroded; the negative plate not at all. It has been found that the actual weight of iron removed may very much exceed the electro-chemical equivalent of the current passed, due, no doubt, to local action. This is shown by the following experiment: Two iron plates were cleaned and weighed previously to being used, and then placed in moist sand containing a little salt. The plates had an immersed area of 11.4 square inches and were 4.25 inches apart. A difference of potential of 1.5 to 1.8 volts was maintained between them for 23¼ hours. At the end of this period the positive plate was weighed and found to have lost .039 of a pound or nearly two-thirds of an ounce. The electric quantity passed was only 8.14 ampere hours. Theoretically this quantity should have removed from 6 to 8 grammes, or nearly one-fourth of an ounce from the positive plate. The actual loss was nearly three times that amount, and the excess is probably accounted for by the great local action taking place on the iron plate when oxidized in patches and placed in an electrolyte, the acid radicle of which is capable of forming a soluble salt of iron.

In a paper read by Mr. I. H. Farnham before the American Institute of Electrical Engineers in 1894 (see *The Electrician*, Vol. XXXIII, p. 16), it is stated that some of the worst cases of pipe corrosion in Boston, U. S. A., occurred when the potential difference of the pipe and rail was only 1.5 volts.

Mr. A. T. Wells of Chicago, in mentioning some cases of cable corrosion which occurred in Cincinnati, stated that the potential between the rail and cable

* Paper read before the British Association at a joint meeting of Sections A and G, Bristol, Eng., Sept. 12, 1898.

* See *Electrician*, Vol. XXXVI, p. 788; also *Electrotechnische Zeitschrift*, March 19, 1896.

was never more than one half, and usually less than one quarter of a volt.

Mr. J. C. Lee of Boston states he has experimentally caused the corrosion of lead and iron by a difference of potential of one-hundredth of a volt.

I have myself produced in a few days sensible erosion of an iron anode placed in moist sea sand, the difference of potential between it and an iron cathode being less than half a volt and the current passing only .03 of an ampere.

These experiments and others of a like character showed that quite small potential differences—much less than 1 volt—between iron surfaces buried in damp soils, especially if soluble chlorides are present, may bring about considerable electrolytic erosion in not very great periods of time, and that there is no absolute security in the limit of 1½ volts as imposed by the Board of Trade, sixth regulation (ii). It was felt desirable to try an experiment on a somewhat larger scale and with actual water pipes buried in the soil. At my suggestion Mr. H. W. Pearson, the engineer of the Bristol Water Company, has carried out at the Bristol waterworks, at Chelvey, an experiment of the following character:

Three rows of new ordinary cast iron 5 in. water pipe were laid down in the ground, one yard apart. Each row consisted of four lengths of 9 ft. pipe, or 36 ft. in all. The lengths were jointed in the usual way with lead and the ends of the lengths were capped with cast iron caps. In each pipe length was screwed a wrought iron rod about 2 ft. 6 in. in length.

These 36 ft. lengths of pipe were buried in the ground 2 ft. deep, just as if they were actual water pipes in use. The ends of the iron standards projected above the ground, and enabled an electrical connection to be made with the pipes at any length. The pipes when buried were clean new cast-iron pipes. Arrangements were then made to keep two adjacent rows of these pipes at a difference of potential of 1 volt night and day for six months. This was achieved by the use of a couple of large secondary cells charged alternately, and which were connected through an adjustable resistance with the two adjacent rows of pipes. A low reading ammeter and voltmeter was provided. The experiment was started on March 1, 1898, and continued for six months. Daily readings were taken of the voltage between the pipes, the current passing between the pipes, and the nature of the weather. The electrical arrangements were placed under the charge of Mr. H. T. Sully.

The arrangement was then as follows: One row of pipes was neutral and simply laid down for comparison to observe the normal appearance of the pipes at the conclusion of the experiment. The other pair of pipes had a difference of electrical potential of 1 volt maintained between them constantly. All three rows of pipes were otherwise under similar conditions and buried in soil of the same kind, a non-acid nearly neutral loam or sandy clay. The average current passing between the two active pipes was 0.15 of an ampere, and varied only between 0.1 and 0.2 of an ampere during the whole of the six months. At the end of the six months the pipes were opened up and carefully examined. The appearance of the pipes was very different. That pipe length which had been connected to the negative pole of the cell was a clean, gray color and had scarcely any trace of oxidation on it. It closely resembled the appearance of the pipe when first put in. The pipe length which had been connected to the positive pole of the cell was uniformly covered with a layer of orange-yellow oxide or hydroxide of iron, in some places of quite sensible thickness and easily detached. The pipe which had been neutral was oxidized slightly in places, but by no means uniformly. The experiment lasted 4,416 hours and 662 ampere-hours had passed from one pipe to the other under a constant voltage difference of 1 volt. The appearance of the pipes clearly indicated that electrolytic action had taken place. In the case of the negative pipe the clean appearance suggested that electrolytic hydrogen had been liberated against it and preserved it from oxidation by contact with the gases, water and salts in the soil. In the case of the positive pipe electrolytic action had clearly assisted or created oxidation. No actual perforations or pitting was found on the positive pipe, probably by reason of the fact that the electrical connections were so made as to facilitate as far as possible a uniform electric flow from one pipe to the other, not specially localized in one place. The actual electric quantity passed, viz., 662 ampere-hours, is theoretically equivalent to the removal of about 3.5 to 4 cubic in. of iron. Since the pipe had a length of 36 ft. and a diameter of 5 in., its surface is approximately 6,500 sq.in. or 45 sq. ft. Hence the oxidation of a comparatively small thickness of the iron uniformly all over the pipe would, electro-chemically speaking, account for the electric quantity passed. The difference between the two pipes amounted in effect to a greater rate of "ageing" of the positive pipe. It is, however, certain that if the electrolytic action, which in this case was tolerably uniformly diffused over the whole pipe surface, had been concentrated at one particular place the erosion would have assumed a more serious aspect.

In the above described experiment none of the conditions served to direct the exit of the current to one limited area on the positive pipe.

It is obvious that if under any conditions of electric traction there are differences of potential between the portions of a continuous pipe buried in the earth, the production of a current of conduction, and therefore perhaps electrolytic erosion, is dependent upon the longitudinal conductive power of the pipes themselves. It has been stated above that ordinary subsoil resistance may be something of the order of 10 to 50 ohms per yard cube. The specific resistance of cast iron is about 100 microhms per cubic centimeter, and would therefore be not far from one-millionth of an ohm per yard cube. It is, therefore, very easy to see that if it were not for the resistance introduced at the joints of the pipes and at the surfaces by rust or oxides, the conductivity of a cast-iron pipe would always be much greater than that of the soil which it displaces.

The resistance introduced, however, by bad or oxidized contacts, or by films of moisture, paint or preservative compound may altogether overbalance or outweigh the resistance of the mere run of the pipe material. I calculate that if there were no joints at all the electrical resistance of a 5 in. cast-iron water pipe would be about 1-50th of an ohm per 100 yards, or say 1-3d of an ohm per mile. If leaded junctions are made in the usual way between fairly clean surfaces the joint resistance may not be large. In the case of the pipe experiment above described, made at Chelvey, I measured at the end of the six months the total resistance of 27 ft. of the 5 in. cast-iron pipe which had been the negative pipe. This length included two leaded joints. The whole resistance was found not to exceed 1-25th of an ohm.

It is obvious, however, that no general statements can be made. It is a matter of great difficulty to measure the resistance *per se* of a pipe buried in the ground, and it is probable that, whereas in some cases the conductivity of long lengths of water and gas pipes may be fairly small, in other cases oxidized or electrically bad joints will introduce great resistance.

We have, however, to regard the subterranean pipes of all kinds as forming a network of conductors, interrupted more or less at places by junctions of high resistance but, on the whole, most probably forming an irregular conductor system of greater conductivity than the soil or earth actually displaced by it or which would occupy the same space if the pipes were not there.

EQUIPMENT AND MAINTENANCE OF ELECTRIC CARS.*

BY M. S. HOPKINS.

(*Concluded from page 184.*)

MOTOR BEARINGS.

Bearings should be run "close" at all times, and the time of their renewal should be determined by the effect of the wear on the gear and pinion, as the wear on these parts is largely affected by the wear of the bearings.

After a series of tests covering quite a period of time, as to the wear of various materials used in motor bearings, the writer feels warranted in making the statement that under the ordinary conditions either the best grade of babbitt or brass bearings should give a longer life than six months, and when a bronze bearing of the proper mixture is used and properly lubricated a life of twelve months can safely be expected. The method of lubrication largely affects the life of brasses. After long tests with various lubricants the writer has discontinued entirely the use of grease on armature brasses, and in most cases on axle brasses, a good grade of engine oil, supplied through wicks, being more satisfactory and economical.

In order to reduce the maintenance of brasses to a minimum the use of phosphor bronze is strongly recommended. Street railways operating twenty-five or more cars will find it economical to cast and machine their own brasses. This may be discouraging to the supply men, but it means money on the right side of the ledger when the expenses are footed up. A small brass furnace can be erected cheaply, and after suitable jigs, which can be attached to any lathe, have been provided for boring and turning, the cost of casting and boring is very little more than the cost of rebabbitting especially where babbitted brasses are machined after boring, while the life of the bronze bearing is far in excess of that of any babbitt yet tried.

Rough and burnt commutators are too frequently cause of expensive motor repairs, and usually indicate imperfect motor design or inexcusable neglect. Well designed motors in good condition, even under the hardest service, should not require turning oftener than once in eight months, provided, of course, the average work is within the rated capacity of the motor. There is nothing that so well indicates to the practical man the condition of the motor as the condition of the commutator. Whenever the commutator shows signs of burning or blackening, steps should be taken at once to prevent it. It is not advisable to try to prevent this by the continual sanding of commutator by motor inspectors, though the occasional cleaning up of the commutator with sand paper is necessary with all motors. The causes of trouble of this character are so numerous that mention is made of only a few of the more important.

The kind of brush used is an important factor. Brushes should be of soft, close-grained carbon treated with a good lubricating compound—one which does not flow too freely from the heat from the motor, and which will not burn and carbonize on commutator. The price of the brush is not a material consideration, as a brush which is slightly superior to another will prove economical even at quite a large increase in first cost. As a rule the tension on the brushes of railway motors is too light. It is a common belief that heavy tension causes wear of the commutator, but experience has shown that the actual wear of commutators, due to the friction of the brush, is very small, and that in some cases increased tension will materially decrease the sparking, which causes the greatest wear. Improper alignment of brush-holders also frequently causes sparking. In

* Read at the Convention of the American Street Railway Association, Boston, Sept. 6-9, 1898.

recent practice the use of side contact springs on brushes has been generally abandoned. On motors carrying heavy currents this spring is quite essential as the excessive heating of the brushes is caused by limited contact in the holder.

Commutator insulation should be made of what is known as the built-up mica segments of the very softest grade of amber mica. A hard, clear mica should never be used in the commutator, as this mica will not wear away as fast as the copper, and there is nothing so disastrous to the life of the commutator as high mica insulation.

In some motors it may be necessary to change the winding of the armature and field coils in order to avoid the burning of the commutator. First, determine by actual experiment what change in winding is necessary, and then equip with the new, winding every armature or field that comes in burned out. The change can thus be made without any great expense, as the greatest part will be borne by the maintenance charge.

THE ELECTRICAL TESTING OF RAILWAY EQUIPMENT.

Elaborate systems for the periodical testing of insulation on railway equipment seems to be growing in favor with some electrical engineers, but the practical value of these elaborate tests is not fully demonstrated. Experience has shown that tests of this kind are very misleading and frequently cause the tearing down of equipment which, under ordinary conditions and had no tests been made, would have continued in service for a long time.

Judging from my own experience, it is neither necessary nor advisable to test periodically the insulation on the equipment, but to make such tests only in cases where the motors are not working properly. The proper training of motor inspectors as to the little points about railway equipment which clearly indicate trouble with motor, will locate in nearly all cases trouble due to weak insulation, so that it can be remedied before any serious damage has resulted to any other part of the equipment.

All armatures and field coils repaired should be carefully tested as to resistance and insulation to ground, and on all armatures having coils repaired, new commutator put on or commutator turned, the resistance between commutator bars should be very carefully measured. This should be done preferably with a portable Wheatstone bridge testing-set capable of showing clearly a variation in resistance of 0.001 ohm. This is one of the most important tests to be made in the care of railway equipment, as more burnouts of armatures are caused by the slight short-circuiting of coils, due to the bridging over of insulation between bars by solder, acid or copper turnings under the leads, than from any other cause. These defects can be located only by a test of this kind. A bad joint or any mistake in connecting up the leads will be detected at once before any damage has been done. For testing insulation to ground I consider a first-class magneto of 10,000 ohms resistance all that is necessary.

TRUCKS.

As the design of trucks varies so widely, very little can be said in a paper of this kind as to the detail of truck maintenance other than to say that all joints should be kept perfectly tight, and where they do become loose the parts should be swedged out and refitted. All bolts should fit tight, and the nuts should be secured by lock washers. In the opinion of the writer, soft, gray iron inset with plugs of soft steel has never been equaled for shoe brakes. The material giving the greatest amount of friction against a chilled surface should always be used, regardless of cost.

Much has been written of late on the subject of car wheels, their wear and alignment, and still street railway managers are careless about their wheels. Too much care cannot be given to the sizing and alignment of wheels and the pressure with which they are forced on the axle. At least 50 per cent. of the wheel renewals throughout the country are caused by broken or sharp flanges or a broken wheel. The use of sand influences largely the life of wheels, but the conditions vary so widely that I would not be justified in saying that in no instance should a sand box be placed upon a car. I will say, however, that where it is possible to successfully operate without them sand boxes should be discarded and other means used for sanding the track. In most cases it is far more economical to fit up a special car capable of carrying a large amount of sand, and sand the track for, say, 100 feet before each point where a stop is likely to be made and on grades and in places where the track is exceptionally slippery, than to sand the rail for its entire length.

REPAINTING OF CARS.

The experience of the writer has clearly demonstrated that it is satisfactory to repaint cars without removing all of the old paint. Patent varnish removers, scalers, etc., are a snare and a delusion. The writer has found the following system of repainting cars to be quite satisfactory: First remove all old paint by softening it with a blow-pot just enough to allow it to be scraped off with a broad putty knife, not allowing flame from the blow-torch to strike the bare wood at any time. Then sand off the surface well with block and sand paper. Where any new work has been put in it should be first primed with a coat of boiled oil and a little lead and allowed to stand for not less than four days. Dashers and all iron work should be thoroughly cleaned with strong alkali and primed with a coat of linseed oil put on boiling hot and allowed to thoroughly harden, giving one coat of oil and lead before color. If the surface is rough, plaster with lead on this coat. Then allow it to thoroughly harden and sand with block; then lay on two coats of flat lead, two coats of color, color varnish, stripe and ornament; finish with one coat of rubbing varnish and one coat of finishing varnish. The main object in the painting of cars should be to secure a hard, smooth surface which will hold out the varnish with the very smallest amount of material; the thinner this surface is the better. Care should always be taken where plaster is used to make it as thin as possible, and lead coats, color and varnish should all be carefully tempered, so as to set alike, as most cases of cracking of paint are due to the want of proper tempering of lead and color coats.

A car painted in this manner should not require repainting for from six to seven years if properly cleaned and varnished. Cars should come into the paint shop, even where the best grades of varnish are used, once every eight or ten months and be washed thoroughly with pumice and strong soap and given a coat of finishing varnish. The life of varnish depends largely on the care given to the cars in the cleaning department. Cars should be sponged off daily with clear water, and any accumulation of dirt removed as far as possible by the use of a chamois skin and sponge—care being taken to rinse off the grit before rubbing with sponge or chamois. Once every thirty days the car should be thoroughly washed down, using a good grade of soap. If it is impossible to remove dirt and stains from the surface of the cars with the finer grades of soap, strong soap may be used, it being found that the injury to varnish resulting from the use of this soap once every thirty days will be more than offset by the saving in cleaning and touching up when the cars are taken into the paint shop for revarnishing.

In the selection of designs for painting of cars the plainest and neatest design should be selected as a rule. No lettering should be done on the panels, as this increases greatly the cost of maintenance in the paint shop department. In all cases the signs should be put upon sign boards made especially for the purpose.

The inside of the cars should be cleaned thoroughly and rubbed down with pumice stone every second time the car comes into the paint shop to be revarnished. There are a number of so-called car cleaners on the market which are rather a detriment than an advantage to the outside surface of the cars, but which may be used to advantage on the interior of the cars, especially around the sash. Special observation of the interior of cars will show that the varnish commences to disappear first around the sash—moisture from the windows gathering around the molding which holds the window sash, first discoloring it and gradually working into the sash itself. A car cleaner which is made up largely of oil and dryer, if used about once a week on the window sash and molding, will be found to be a great advantage. Three years ago four new cars were selected, and a car cleaner used weekly on the windows of these cars, and to-day not a stain is to be seen on sash or molding, the cars having been revarnished twice during that time.

After a number of trials of various floor paints and paints mixed especially for the purpose the conclusion has been reached that there is nothing equal to pure white lead and linseed oil and suitable color for the floors of all cars. The majority of car floors are stripped, and it has been found impossible to find any material hard enough to stand on the top of the strip of a car floor, while almost any material will stand the wear, but not the moisture, between the slats. It is very evident, therefore, that the best paint for this purpose is one which will best preserve the wood in the floor of the car from the constant moisture to which it is subjected.

As to the car roofs, the main object is to put as little material as possible on the canvas of car roofs, and that material should be elastic and yet withstand the action of the weather. Great care should be used in tempering of paints for roofs. Avoid painting the roof one time with one kind of paint and the next time with another, for in the long run this will invariably crack and require the renewal of the canvas on the roof. In a number of cases it is customary to use slush or any old thing which happens to be in the paint shop for painting roofs of cars. This is a great mistake, for no paint is too good for the car roof—the best white lead and oil giving the best results.

Unquestionably the truck of car should be painted with a good grade of lead paint, as it prevents rust, decreases renewal of bolts and adds greatly to the general appearance of the car. A handsomely painted car body mounted on a dingy, rusty-looking truck has a half-finished appearance, to say the least.

Magnetism and Temperature.

Mr. J. R. Ashworth, B. Sc., in a paper read before the British Association, "On the Construction of Magnets of Constant Intensity under Changes of Temperature," describes experiments on a remarkable property of drawn steel wires. Magnets made of such wires, after a series of heatings and coolings, reach a cyclic state in which, contrary to general experience, an increase of temperature produces an increase of magnetic moment, and decrease of temperature a decrease of magnetic moment. It is easy, by several processes which are described, to change this abnormal effect to the normal one, in which higher and lower temperatures produce lower and higher magnetic moments respectively. In passing from the abnormal to the normal state by any of these processes, a stage is reached at which change of temperature neither increases nor decreases the magnetic moment, and for changes within the atmospheric range of temperature, the intensity of such a magnet remains constant. An account is given of the behavior at different times of magnets of constant intensity which have been tested at intervals during eighteen months. In conclusion, experiments on the cause of the abnormal thermo-magnetic effects are described.

AMERICAN STOKERS AT UNION STATION

Edison Electric Illuminating Co., Brooklyn, N. Y.

Among mechanical stokers and patent furnaces, the American stoker, introduced by the American Stoker Company, Washington Life Building, New York City, stands alone as a practical exponent of the principle of underfeeding of coal. That it is built upon attractive lines is evident from its wide and rapidly extending adoption in power plants of prominence and magnitude in all parts of the country.

The principle upon which the American stoker operates, practically reducing the coal to gas and coke, insures complete combustion, and guarantees entire freedom from smoke and soot. It will burn any grade of coal from the finest slack coal to lump of any size that can be fed into the hopper, the constant feeding doing all the stoking necessary.

A good example of the efficiency of the American stoker is found in its use at the plant of the Edison Electric Illuminating Company, Brooklyn, N. Y., which is destined to be one of the largest electrical power plants in the world, plans having been made for a 60,000 horse power station, and about one-fourth of the plant has already been completed. The boiler room, 198 x 46 feet, is equipped with boilers of the Cahall water-tube type, each with a nominal capacity of 500 horse power. The boilers are furnished with the American under-feed stokers, three stokers independently driven being installed for each furnace.

Slack coal for the furnaces is received upon boats at the foot of a dock and carried by cars to storage bins. From these bins it is elevated to smaller bins just above the boiler floor, and from these distributed through chutes to the several conveyors carrying it to the stokers. Chutes leading from the boiler house bins terminate in a weighing apparatus which automatically registers the amount of coal passing through.

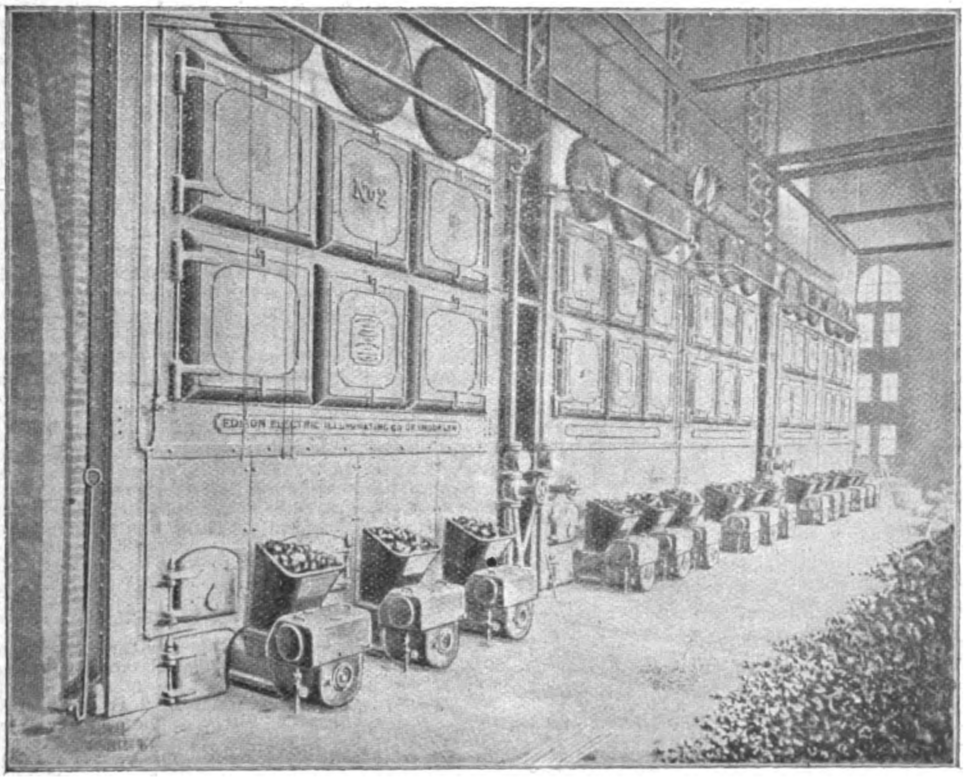
The illustration herewith, showing the boilers and stoker arrangement, was secured before this coal conveying apparatus was installed.

Passing through the weighing apparatus the coal is distributed by two conveyors to three mechanical stokers on each side. These conveyors are driven by an electric motor located on the upper front edge of the boiler front. Immediately beneath the coal hopper of the stoker is a conveyor pipe which communicates with the coal magazine placed in the furnace of the boiler. A screw conveyor, or worm, is located in the conveyor pipe and extends the entire length of this magazine. Immediately beneath the conveyor pipe is located the wind box, having an opening beneath the hopper, and through which the air supply for the furnace is forced. The other end of this wind box opens into the air space between the magazine and outer casing. The upper edge of the magazine is surrounded by tuyeres, or air blocks, which are provided with openings for the discharge of air inwardly and outwardly.

Each stoker is driven independently by a small steam motor attached to and located in front and beneath the hopper. The motor has a simple reciprocating piston which is so connected as to turn the conveyor shaft which forces the coal into and up through the magazine.

The stoker is entirely self-contained and complete in itself. The rate of feeding the coal is controlled by the speed of the motor, this being effected by the simple means of throttling the steam in the supply pipe to the motor. The coal fed into the hopper is carried by the conveyor into the magazine which overflows on both sides and spreads upon the sides of the grates. The coal is fed slowly and continuously and approaching the fire in its upward course is slowly roasted and coked. The gases released from it are taken up by the fresh air entering through the tuyeres, which consumes these gases and delivers the coal as coke on the grates above. Every pound of coal fed into the hopper is subjected to this gas making process, and there is no loss of coal through grates by reason of the use of dead grates in the furnace in place of open grate bars.

The complete combustion produced by this method is appreciated when viewing the stack of the plant, from which there is no smoke.



American Stokers at Union Station, Edison Co., Brooklyn, N. Y.

The Chicago Electrical Association.

Below will be found the Fall programme for 1898 of the Chicago Electrical Association. The meetings will be held at 1736-41 Monadnock Building:

October 7, 1898—"Electrical Features of the Late Spanish-American War," by Thos. G. Grier, Western Electric Co.

October 21, 1898—"Practical Points on Electrical Measurement," by W. B. Hale, Cable Testing Department Western Electric Co.

November 4, 1898—"The Electrical Equipment of a Model Printing Establishment," by George A. Damon, Electrical Engineer with B. J. Arnold.

November 18, 1898—"The Development of the Motor-Cycle," by F. B. Rae, Electrical Engineer.

December 2, 1898—"Practical Points in Street Railway Engineering," by W. A. Harding, Master Mechanic and Electrician Calumet Electric Street Railway.

December 16, 1898—An address by Arthur V. Abbott, Chief Engineer Chicago Telephone Company, on "Wireless Telegraphy" (illustrated by apparatus).

January 6, 1899—"Telephone Engineering—Some Problems, Solved and Unsolved," by S. G. McMeen, Chief Engineer Central Union Telephone Co.

January 20, 1899—"Observations on Ventilating Fans," by Gerard Swope, Western Electric Co.

The officers of the Association for 1898—are F. S. Hickok, President; T. G. Grier, Vice-President; E. J. Swartout, Treasurer; J. R. Cravath, Secretary; S. G. McMeen, J. M. Hollister, C. Wiler, directors.

LEGAL NOTES.

Judge Swan of the United States District Court at Detroit, Mich., has just decided that the lapsing of a foreign patent after the filing of the application for a United States patent, but before its issuance, does not affect the term of the subsequent United States patent.

In the infringement suit brought at Detroit by the Sprague Electric Motor Company against the Detroit Citizens' Street Railway Company, Judge Swan has issued an order for a preliminary injunction restraining the railway company from using the motor alleged to be an infringement of the Sprague patent. Another order issued by the Judge suspends the injunction long enough to enable the railway company to remove the apparatus from its cars. Within 30 days 250 must be removed, within 60 days 250 more, and within 90 days the balance. Sworn statements are required at the end of each of these periods that the work has been performed as ordered.

CANADIAN NOTES.

It is reported that Edward S. Jennison, a Chicago engineer, has a plan to dam the Kakabeka river at a cost of $1,000,000 and to utilize its power for the benefit of Port Arthur and Fort William, Ont. The intention is that the towns of Port Arthur and Fort William shall get their water supply from this source, which will likewise give them a fire pressure by gravitation. The water will, it is said, be sufficient also to generate electricity to supply power to the Port Arthur electric railway as well as electric light and energy to both towns.

Application has been made to the Ontario Legislature for an act to incorporate the Toronto Elevated Railway Company, such act to provide that the company may, subject to the consent of the municipalities affected and subject to all other existing rights, construct and operate a system of elevated electric railways in Toronto and adjoining municipalities, and also in conjunction therewith a system of surface railways in Toronto and other municipalities within a radius of 50 miles.

The annual meeting of the Standard Light & Power Company was held this week at the office of the company in Montreal. The annual report of business for the past year was considered highly satisfactory, being the most successful year since the company's incorporation. A contract has been entered into with the Lachine Rapids Hydraulic Company for supplying current to run their plant from the Lachine Rapids in place of steam. It was decided to largely improve the station by purchasing rotary converters, fire proofing the building and making the station the most complete direct current station in the Dominion. In addition to receiving power from the Lachine Rapids, there is also a magnificent steam plant in reserve, so that their customers are doubly protected.

THE NEWS.

What Is Going On in the Electrical World.

LIGHTING.

Abbeville, S. C.—An electric light plant for this town is being considered by prominent business men.

Charlestown, W. Va.—The directors of the Charlestown Electric Light, Heat & Power Company have, it is stated, decided to purchase a new dynamo for incandescent lighting and will change to the alternating system. Mr. Hostetter has resigned as manager and been succeeded by F. P. Unger.

Clyde, N. Y.—L. L. Moses of the Clyde Electric Company, representing a syndicate, has submitted a proposition to the common council of Geneva to light that city for ten years.

Fredericksburg, Va.—The council has unanimously adopted the report of the committee on light advising the erection of an electric lighting plant by the city. Bids will be asked for and a special election held to get a vote of the people on their acceptance.

Grand Rapids, Mich.—The board of public works has awarded the contract for the complete installation of an electric lighting plant to the Chase Construction Company of Detroit for the lump sum of $89,970.

Herkimer, N. Y.—The municipal commission having sent a communication to the board of trustees requesting the board to call a special election for the purpose of allowing the citizens of the village an opportunity to vote on a proposition to bond the village for $13,000, the money to be used in establishing an incandescent electric light plant, the board in compliance with the request has ordered an election to be held October 10.

Independence, Mo.—W. T. Felton of Kansas City proposes if granted a franchise to put in an electric light plant here and furnish the city with arc lights and a full night service for $90 a year per lamp. The present company charges $75 per light based on a moonlight schedule and shuts off the light promptly at 12 o'clock, leaving the city in absolute darkness.

Milwaukee, Wis.—The council of South Milwaukee has adopted a resolution providing for the purchase of the plant owned by the South Milwaukee Electric Light & Power Company. Payment is to be made in monthly installments until these amount to $19,000, when the company is to deed the plant to the city for $1. This course was rendered necessary because the city is already bonded to the debt limit.

Morenci, Mich.—The village council has accepted the proposition of S. A. Scofield & Sons to light this village with electricity. The firm has a fine electric plant and already furnishes light for nearly all the business places.

Montpelier, Vt.—The Consolidated Lighting Company has added a Stanley dynamo of 200 horse power to its plant. It will be used in furnishing light for the State House.

New York.—The Edison Electric Illuminating Company of New York has issued a circular to its customers announcing a reduction in rates on bills due after October 15. The new rates as stated in the circular will be: 20 cents per kilowatt hour (equivalent to one cent per 16-candle power 50 watt incandescent lamp hour, or 10 cents per standard arc lamp hour) for first hour's daily use; 15 cents for second hour; 10 cents for the third and fourth hour and 5 cents for all use above four hours. For wholesale use, 10 cents per kilowatt hour for the first four hours and 5 cents for all use above four hours, with reduction for quantity. These prices will be made for the period October-December, 1898, with the intention, should results justify, of making them permanent and possibly of still further reducing rates for long-hour use or making a maximum rate equivalent to ¾ cent per 16 CP. incandescent lamp hour. Contracts will be made at the above prices, however, for a full year. Plans to reduce rates for power service are under consideration.

Orlando, Fla.—The electric light company that promised to give Orlando a full fledged plant by May 1 last seems to have met with obstacles. Poles were secured and set for the wires, a building was erected, and now the engine, boiler, dynamos and other machinery are there, but no one to pay the freight and claim the property. It has been claimed that the property has not been paid for, and is still owned by the shippers.

Patchogue, L. I.—The Patchogue Electric Light Company is contemplating the extension of its lines through the Long Island villages of Blue Point, Bayport and Savville. The company at present only supplies the village of Patchogue. Should the plan of the company mature, as it will without a doubt, the company will increase their capital stock from $20,000 to $30,000 in order to meet the expenses of the change.

Port Chester, N. Y.—The Port Chester Electric Lighting Company has just purchased the plant and franchises of the Westchester Gas & Electric Company and will begin in a short time to build an entirely new plant to supply the villages of Port Chester, Rye, Harrison and Mamaroneck. The capital stock of the new company is $50,000, and the officers are William E. Ward, president; J. Addison Johnston, vice-president; William L. Ward, treasurer, and Walter S. Comby, secretary.

Seattle, Wash.—Dawson, Alaska, is to have electric lights this winter. A full plant, including five dynamos and apparatus for operating twenty arc and 2,000 incandescent lamps was taken on the steamer Dirigo that has just sailed for Lynn canal. The outfit weighs thirty-five tons. There is a small outfit already at Dawson, which was expected to be operating 800 incandescent lamps by September 15. G. M. Easterly is the superintondent of the works.

Sturgis, Ky.—An electric lighting plant is to be established here shortly by a local company who propose to put in a system at their works of sufficient capacity to light the town.

Tekoa, Wash.—The electric light plant owned by Frank and Edward Mahoney was damaged by fire on the 20th ult., much of the machinery being rendered unserviceable.

Utica, N. Y.—The Utica Electric Light Company is increasing the capacity of its plant and has ordered two 125 arc light dynamos, a 250 KW. generator and a 1,000 HP. Corliss cross compound condensing engine.

Wharton, Tex.—A company represented by G. C. Gifford has been granted a franchise by the town authorities for a water and electric light plant, and the purpose is to erect the plant and put it in operation at the earliest possible moment.

STREET RAILWAYS.

Alton, Ill.—President Porter of the Alton Railway & Illuminating Company declares that his company intends to spend at least $50,000 in the extension of its plant here next year. The plans include the adding of fifteen new pattern electric cars and the laying of ten miles of new track, including a line to East Alton.

Baltimore, Md.—Surveyors are now engaged making an estimate of the cost of construction of the proposed line of electric railway which is to run from Baltimore through Anne Arundel county to Gibson's Island, or Mountain Bar, as it is sometimes called, on the shore of the Chesapeake bay, 14 miles from Baltimore. A certificate of the incorporation of the company has been filed at Annapolis, and the Commissioners of Anne Arundel county have adopted a resolution granting the company the use of the necessary public roads and bridges. The capital stock of the company is $50,000, and the incorporators named are Frank S. Revell, Elijah Williams, F. Eugene Wathen, George E. McDonald, Frank L. Hancock, B. R. Anderson, Robert Moss and James P. Bannon of Anne Arundel county; Walter R. Townsend of Baltimore county and James Bond and John F. Williams of Baltimore City.

Boulder, Col.—The city council has granted a franchise for an electric car line in the city to W. C. Dyer, J. W. Dean, E. C. Allen and Guy D. Duncan.

Butler, Pa.—At a public meeting held here a few nights ago, a resolution was passed to the effect that it was the sense of the meeting that a street railway is desired, and that council be recommended to grant a franchise with proper restrictions. It is likely that an effort will be made to come to terms with the company from Warren, Pa, which already has a charter.

Cleveland, O.—The Consolidated Traction Company is introducing electric heaters on its cars.

Clinton, Mass.—The Clinton, Hudson, Maynard & Concord Street Railway Company has filed with the selectmen its bond for $10,000 to fulfil the requirements of the franchise and have the road in operation within eighteen months.

Haverhill, Mass.—The strike of electric car employes here, due to the company requiring conductors, etc., to furnish indemnity bonds, is about closed as many of the men have returned to work and the cars are running on schedule time.

Kansas City, Mo.—P. D. Armour of Chicago has recently largely increased his holdings in the Metropolitan Street Railway, and N. B. Ream of the same city has purchased a large block of the stock from Robert Fleming of London and has been made a director. The earnings of the company have shown a gradual improvement in the last year and are now understood to be equal to 7 per cent. on the capital. It is believed here that Armour and Ream desire to gain control of the entire street railway system of Kansas City, and that they will make many improvements and extensions, changing the cable roads to electric.

Knoxville, Tenn.—Frank S. Hambleton of Baltimore, president of the Knoxville Traction Company, and a number of Baltimore and New York capitalists interested in the Knoxville street railway system were given a public reception at the Imperial Hotel on the evening of the 27th ult. It was one of the most imposing affairs in the history of the city and originated in the desire of the business men to entertain the men who in giving Knoxville superior street railway facilities and in other ways had done so much to build up the city. Gen. C. C. Howell, vice-president of the Knoxville Traction Company, introduced the visitors to their entertainers.

Laurel, Md.—The establishment of a public park at Brashear's Springs and an electric railway from Savage to the Springs is being promoted by Mayor Edward Phelps and some Baltimore capitalists.

New Hartford, N. Y.—The trustees have voted to grant a franchise through the village to the Sauquoit Valley Electric Street Railway Company, a condition being that the fare to Utica shall be not more than five cents.

Rochester, N. Y.—The local directors of the Sodus Bay Electric Railway Company, as the result of a conference with the highway commissioners, have secured right of way along the Ridge road to Sodus.

Rockford, Ill.—The Rock River Construction Company, which has taken the contract to build the Rock River Electric Railway, agrees to have the line completed from Rockford to Oregon, a distance of thirty miles, by January 1.

Steubenville, O.—Preliminary surveys have been completed for a new street railway line between this city and Mingo Junction, and the line will likely be built within the next few months. It is asserted that the line is to be part of the system which is to connect Pittsburg with Wheeling by way of the towns along the Ohio river.

Terre Haute, Ind.—A trolley line is being promoted to run between Terre Haute and Merom, thirty-two miles.

Washington, D. C.—The contract for equipping the City & Suburban Railway, formerly the Eckington, has been awarded to E. Saxton of this city. Mr. Saxton has done all the work of equipping the street railways in Washington that have changed their motive power to a modern system. He has also done considerable work in this line in New York City.—It is expected that the stockholders of the Columbia Street Railroad Company will hold a meeting early this month for the purpose of granting the necessary authority for the issue of bonds which will be needed to furnish the money required to construct the proposed eastern extension of the road out Benning road to the District bounds. It is also understood that at the same meeting the stockholders will be called on to approve the plan of changing the cable motive power on the present line to the underground electric system, so that the entire road will be operated by electricity. It is estimated that the entire cost of the proposed work, including the fitting up of the power house, will be about $450,000, and it is expected that bonds to that amount will be issued.

York, Pa.—It is understood here that the new management of the York Southern Railroad Company intend to change the branch line running from Delta to Peach Bottom into a trolley road, the power to be supplied by the Delta Electric Power Company.

MANUFACTURING, ETC.

Detroit, Mich.—A fire which broke out in the building occupied by the Michigan Electric Company, on the 24th ult., almost entirely destroyed the stock of the company, valued at $50,000. It was fully insured.

New York.—The "Journal of Commerce" of September 29 says: "The demand from Italy for certain manufactures is making satisfactory progress. Upwards of 21,000 worth of electrical material has been purchased this week in the local market by shippers to Genoa. Exporters interested in the trade claim that in the electrical line orders will be forthcoming to a greater extent during November and December on account of the advancement being made in many districts of the country with which home products cannot possibly cope. American manufacturers are at present actively engaged in sending estimates of some magnitude through their European agents."

TRANSMISSION PLANTS.

Porterville, Cal.—W. H. Hammond has returned from England, whither he went to obtain financial backing for a scheme to develop electrical power for irrigation and other purposes. The plant will be established twenty-nine miles east of Visalia on the Kaweah river. The estimated cost of putting in the plant and extending the system to Visalia, Tulare, Porterville and Lindsay is $250,000.

COMPANY MATTERS.

Columbus, O.—A dispatch from Fremont, O., states that "one of the biggest deals ever engineered in Fremont is about to be consummated. By the transaction Eastern capitalists will acquire possession of the Northwestern Ohio Mutual Gas Company's plant in Fremont, also the plants of the Fremont Electric Light & Power Company, the Fremont Gas Company, the Creager Light & Power Co., and the Fremont Street Railway Company. All of the above plants are to be merged into one and managed and operated under one head."

PERSONAL AND MISCELLANEA.

John Leach, an engineer at the Evansville, Ind., electric light plant, on the night of the 24th ult. fell into the running machinery and was instantly killed.

John H. Moffit, general manager of the Syracuse (N.Y.) Rapid Transit Company, has resigned. It is thought likely that his successor will be C. Loomis Allen, engineer of the road.

Samuel L. Gilmore of Lewiston, Me., a lineman on the Lewiston, Brunswick & Bath electric road was killed recently by a shock from an 18,000 voltage wire. He was at work repairing a wire about three miles from Lewiston when the accident occurred. Gilmore was about 30 years of age.

Col. Eugene Griffin of the First Regiment Volunteer Engineers and vice-president of the General Electric Company, who returned sick from Porto Rico on the transport Concho, which arrived at New York several days ago, is not yet fully recovered from the attack of fever which prostrated him.

At Albany, N. Y., a few nights ago, a lad named Jeremiah Kennally was struck dead by an electric shock

which he received while endeavoring to get a light for his cigarette from an arc light in a music garden. As soon as Kennally touched the light he fell to the ground and died almost instantly.

A special to the Denver "News" from Salt Lake, Utah, states that a test of the Whitehead electric volley gun, the invention of a Salt Lake man, was made on the 16th ult., in the presence of a number of Eastern ordnance experts and Prof. D. C. Hanish of London. The test demonstrated that the twenty-barrel gun would discharge upwards of 10,000 shots per minute. The projectiles are of a special pattern, being the invention also of Mr. Whitehead. The experts were satisfied by the test, and pronounced the invention superior to any machine gun now in use. Several of the guns will be made by a Connecticut firm at once, and a test will then be made by the War Department.

Alexander Graham Bell, the inventor of the telephone, arrived at San Francisco, Cal., two weeks ago on his way to Japan. He was accompanied by his wife and daughters and sailed for Yokohama on the steamship Coptic. In conversation with a representative of the "Call" he said: "I have not given the telephone much attention of late, for I have not been connected with any telephone companies during the last fifteen years. Aerial navigation and its multitudinous problems have absorbed my time to the exclusion of all other scientific questions. I am now preparing a series of papers on the subject of aerial locomotion for the National Academy of Science. They will be published soon after my return to this country. Aerial navigation is coming; it is almost here. I was a witness of the first practical aerial test made—that of Prof. Langley with his aerodrome propelled by steam, and we may soon expect great strides in this line of invention."

A correspondent of the Cambridge, Mass., "Tribune" has been visiting Chillicothe, Ohio, lately, and had there his first cognition of a woman street-car conductor. He boarded a car the conductor of which was "an exceedingly attractive specimen of the fair sex," and gives his impressions as follows: "At first I supposed that this was some special graft of the Young Women's Christian Association, and that 'the proceeds of the day were to be devoted to the Soldiers' Aid Association,' or some other equally laudable beat, and I looked carefully through my pocket for something smaller than a quarter before I proffered my fare, as I anticipated 'there would be no change on this special occasion.' But I was in error, for a ten-cent piece and two nickels were extracted from the leather bag the young woman wore at her waist-belt, and I received my change with a blush at my unwarranted suspicion. A series of inquiries from my neighbor in the car resulted in discovering that the Chillicothe Street Railway Company have in their service seven young women (my informant, who was a gay youth with a red necktie and a general air of levity, characterized them as 'mainly daisies') who are performing their arduous duties in a thoroughly polite, conscientious and satisfactory manner, commanding the respect of all (and the evident admiration of my youthful friend), while working nine hours daily, with one day off in seven, and receiving for their labor the altogether preposterous remuneration of $4 per week! I did not fail to observe that the young woman who personally conducted my car was neatly and suitably dressed and that she managed to keep her hands clean—a saving grace that seems absolutely unattainable to the average male street-car conductor."

COMMERCIAL PARAGRAPHS.

From all accounts the Electrical Engineer Institute of Correspondence Instruction, 120 Liberty street, New York, is prospering. There are three excellent courses of study offered by this Institute to those who desire to obtain an electrical education but who cannot well spend the time to attend a college. The junior course, in which the simple mathematics and elements of electricity are taught, costs $55, payable in monthly installments of $2. For the senior course the charge is $75, payable in like manner. A more advanced course is offered to those desiring to become proficient in the design of continuous and alternating current apparatus, for which $55 is charged, payable in $2 monthly installments. We understand the instruction papers of this Institute have been carefully compiled by some of the leading engineers in the electrical profession. A correspondence school such as this should undoubtedly prove of value to a large number of persons who are employed during the day and have only the evening in which to study.

The growing demand and the popularity of the Power Pump manufactured by Goulds Manufacturing Company of Seneca Falls, N. Y., has made it necessary for the company to greatly increase the number and variety of its patterns. In a catalogue recently issued by this well-known concern a large number of different types of Power Pumps are fully illustrated and described, as well as a number of pumps now in actual operation for special purposes. The catalogue will be sent to those interested on request. The branch offices of this company are at 16 Murray street, New York, 8 Oliver street, Boston, and 22-24 North Canal street, Chicago.

Owing to a disastrous fire on September 24 which destroyed their offices the Michigan Electric Company, Detroit, Mich., announce that they have leased temporary quarters at 106 Woodward avenue, where arrangements have been made for carrying on business as usual. A new stock of electrical material is already on hand, so that there will be no delay in the filling of orders. Work on permanent quarters is now being pushed with all possible speed, and in a very short time this well-known company will be in better condition for business in all departments than ever before.

The Carborundum Company of Niagara Falls, N. Y., have now ready for distribution an exceedingly attractive catalogue descriptive of their goods. In this book, which contains over sixty pages, is described and illustrated the various productions of this concern as well as a large variety of goods manufactured out of carborundum. These include cloth, paper, rubbing bricks, scythe stones, and drum wheels for use in the making of gloves. The New York representative of the Carborundum Company is Mr. Emil Ulrich, 136 Liberty street.

We are in receipt of an interesting and attractive booklet recently gotten out by the Graham Equipment Company, 170 Summer street, Boston, describing the well-known Graham Steel "I" beam truck. The main stress member of the side frame of this truck is a Carnegie steel I beam, weighing 10 lbs to the foot. This beam runs the entire length of the truck, and forms a continuous support for the car body, which is rigidly bolted to it. No spring base is used, the flexible suspension being confined entirely to the axle-boxes. The use of the I beam frame permits securing the pedestals and motor supports by single bolts and makes the side frame very rigid and stiff, without the use of either bolted or riveted joint.

It is the simple and logical application to truck building of the most approved transverse stress member in bridge and roof construction.

The center cross member is a 5" steel channel, held fast by two ¾" rods, the end cross members being 3" extra heavy steel tubing, with ¾" rods through the center. The rods bind the two side frames together, making the strongest, lightest and simplest truck frame ever built.

These trucks are now being sold at $150 each, and how highly they are thought of may be gathered from the following letter:

Winchester Ave. R. R.,
West Haven, July 18, 1894.

The truck gives perfect satisfaction. I consider it the best truck on the market, and the president and board of directors say it is the finest riding truck they ever rode on.
Yours truly, ALBERT E. POND, Supt.

The Electric Appliance Company, Chicago, have taken the general Western agency of the Utility Shade Company, manufacturers of the Utility Shades in paper and celluloid. These shades are something quite new in the electrical line and are destined to find a very large field as they possess a great many points of merit, among which may be mentioned the following: They are very light in weight, neat in appearance and practically indestructible. They require no separate shade holder and are low in price. They are made in a number of different shades and colors. The Electric Appliance Company have issued a special catalogue of these goods, which they will be pleased to send to the trade upon application.

The Warren Electric & Specialty Company of Warren, Ohio, well-known manufacturers of High-Grade, Anti-Trust Incandescent Lamps, have recently gotten out an attractive blotter in which they say:

POINTERS WITH A POINT.

No. 1. Who furnished four thousand two hundred and twenty volt lamps for the new steel pier at Atlantic City? We did. Were they satisfactory? Write the management there and see.

No. 2. Woman leads the world. She used smokeless powder for ages before men thought of inventing it.

No. 3. Who sold ten thousand lamps to the Masonic Temple in Chicago? We did.

No. 4 Science has discovered microbes in kisses. This shows the microbe is not such a fool as he looks.

No. 5. If we can please such large and critical buyers as the above, don't you believe we can please you? We will try hard. Try us please. We have a strictly high-grade lamp at a close price.

No. 6. Better save your burned-out lamps and bases and when you have 250 write us. They are worth money.

The Schieren Booth at the Omaha Exposition.

One of the most attractive booths in the Machinery and Electricity Building at the Trans-Mississippi Exposition is that of Chas. A. Schieren & Co., in the busy northwest corner of the building.

The most prominent feature of the exhibit is a monster perforated electric belt 72 inches wide. This is one of a great number of belts of that size manufactured by Chas. A. Schieren & Co., and is a striking example of the art of making large belts, in the manufacture of which this firm excels.

At one side of the booth an immense hide is suspended, intended simply to exemplify their justly celebrated Dixie tannage. Alongside is a picture of their famous Dixie tannery, Bristol, Tenn. The capacity of this tannery is 60,000 heavy hides per year. It is located in the heart of one of the best oak bark regions of the country. The tannage is the old long process with pure oak bark. This, together with their high order of workmanship, is conclusive of the fact that they secure to their belts the longest possible life and wear in leather belting. There are several rolls of their high-grade short-lap belting on exhibition.

The electric and perforated electric belting is well represented. This, the perfection in belting for dynamos and other swift-running machinery, is too well known to need any description here. It is to be found in use in every city and almost every town in this country and also very extensively in Europe, South America, Asia, and in fact all over the world.

There is also a roll of link belting, showing the patent American joint, which enables the belt to conform perfectly with the crown of the pulleys and to run perfectly on odd drives, as for instance a "quarter turn" Another of this firm's many contributions in the line of progress to be seen at the Exposition is their "Giant" lace leather. This is unique in color but is gotten out solely for strength and durability, and the demand for it is conclusive proof of its great and uniform success.

It is a significant fact that on oak backs, bellies and shoulders, which are also represented in their exhibit, Messrs. Chas. A. Schieren & Co. justly enjoy the same reputation among shoe manufacturers as upon leather belting and lace leather in the immense community of belt users.

The exhibit includes also Pump and Valve leather, Round Solid, Twist and Patent Solid belting, Electric Belt Dressing and Cement.

A visit to this attractive booth (see illustration) is bound to prove instructive to all users of leather, and the interesting literature dispensed as souvenirs will commend itself to all seeking information in this line. Mr. Herman A. Giese is the representative in charge.

We are in receipt of two handsomely gotten up catalogues recently issued by the New Britain Machine Company of New Britain, Conn. One of these describes in detail the Case Automatic High-Speed Engine and contains some forty pages. It is fully illustrated with half-tone cuts and there are several useful tables showing the horse-power, speed, floor or other space required, etc. The sec

ond catalogue is devoted to a description of the Chain Saw Mortiser manufactured by the same concern. The various types of mortisers are shown with a description of each. In each case the specification is given as well as a short table showing exactly what that special type of chain saw mortiser will accomplish. The last few pages are devoted to a number of very favorable testimonials. In short, these two catalogues describe in an attractive manner the high grade goods for which this company has been enjoying a large domestic and foreign demand.

RECENT COMPANY ELECTIONS.

Philadelphia Traction Company, Philadelphia.—President, George D. Widener; vice-president, William L. Elkins; secretary and treasurer, Alexander Rennick; directors: P. A. B. Widener, William L. Elkins, Thomas Dolan, James McManes, J. B. Altemus, George W. Elkins.

Union Traction Company, Philadelphia.—President and general manager, John B. Parsons; vice-president, George D. Widener; secretary and treasurer, Charles O. Kruger; directors: John B. Parsons, George D. Widener, Peter A. B. Widener, William L. Elkins, Thomas Dolan, James McManes, Alexander M. Fox, Jeremiah J. Sullivan, Alfred Smith, William H. Shelmerdine and George W. Elkins, the last named being elected to fill the vacancy caused by the retirement of John Lowber Welsh.

INCORPORATIONS.

The Eureka Electric Company, Chicago, Ill. Capital stock, $10,000. Incorporators: J. Kusel, Arnold Cohn and H. J. Kusel.

The McKinney Electric Light & Motor Power Company has been incorporated at Austin, Texas, its purpose being to supply electricity to the public for all purposes. Capital stock, $17,000. Incorporators: L. A. Scott, J. P. Nunciey and D. T. Pardue.

The Georgia Heating & Lighting Company, Atlanta, Ga. Capital stock, $10,000. President, J. F. Burk; secretary and treasurer, Dr. R. J. Thurmond; directors: J. F. Burk, R. J. Thurmond, R. H. Wilhoyte, W. A. Ellis and W. T. Glacon.

The Missouri Electrical Railway Company, Kansas City, Mo.—to build and operate street railways in Kansas City, Jackson and adjoining counties, the motive power to be electricity, compressed air or cable, and to deal in street railways and street railway securities. Capital stock, $500,000, divided into 100,000 shares of $5 each. Stockholders and directors: Chett McDonald, Henry Smith, Benjamin F. Burd, William H. Brown and Frank W. Sears, all of Kansas City. Mr. Sears holds 99,200 shares.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED SEPTEMBER 27, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

611,271. Electric Railway. Oscar Preil, Washington, D. C., assignor to the Wheless Induction Railway Company, same place. Filed Dec. 30, 1897.

611,367. Trolley-Pole. Albert M. Meredith, Philadelphia, Pa., assignor, by direct and mesne assignments, to George Grant Armor, Baltimore, Md. Filed March 31, 1897. Renewed July 16, 1898.

611,481. Motor-Mounting for Electric Cars. Sidney H. Short, Cleveland, O. Filed June 26, 1897. Renewed May 19, 1898.

611,559. Electric-Railway System. George L. Campbell, Dushore, Pa. Filed Oct. 29, 1897.

ELECTRIC LIGHTS AND APPLIANCES.

611,460. Electric-Arc Lamp Timothy H. Pettengill, Amsterdam, N. Y. Filed Sept. 4, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

611,273. Means for Supporting Electric Motors. Louis T. Pyott, Philadelphia, Pa. Filed May 14, 1897. Renewed Feb. 23, 1898.

611,465. Controller for Electric Motors. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed April 19, 1898.

611,501. Mechanism for Imparting Successive or Alternating Movements. Elisha Moore, Meductic, Canada. Filed Feb. 3, 1898.

611,558. Apparatus for Starting Motors. James Burke, New York City, assignor to the Bullock Electric Manufacturing Company of Ohio. Filed April 4, 1898.

TELEPHONE AND TELEGRAPH APPARATUS.

611,448. Apparatus for Printing Telegraphic Messages. Godfrey M. Gibson, Chumleigh, England. Filed Nov. 10, 1896.

611,581. Telephone System. Georg Ritter, Stuttgart, Germany. Filed Feb. 23, 1895.

MISCELLANEOUS.

611,243. Safety-Fuse for Electric Circuits George W. Gardanier, Nyack, N. Y., assignor of three-fourths to David G. Black, Lake Hill, N. Y., and Thomas J. Smith, Roselle, N. J. Filed Dec. 16, 1897.

611,258. Truss-Frame for Electric Vehicles. Karsten Knudsen, Chicago, Ill., assignor to the American Electric Vehicle Company, same place. Filed Oct. 20, 1897.

611,466. Alternating Current Measuring Instrument. Harry P. Davis, Pittsburg, and Frank Conrad, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Filed May 7, 1898.

611,592. Alternating-Current Voltmeter. Harry P. Davis, Pittsburg, and Frank Conrad, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company of Pennsylvania. Original application filed May 7, 1898. Divided and this application filed June 18, 1898.

DESIGN.

29,410. Transformer-Case. Frederick C. Sutter, Swissvale, Pa. Filed Aug. 6, 1898.

TELEPHONE AND TELEGRAPH.

The Telephone Deal in Minnesota.

The St. Paul *Pioneer-Press* of the 21st ult. gives some further particulars relative to the telephone deal in Minnesota. It says: "The Northwestern Telephone Exchange Company yesterday closed a deal by which it acquires control of the independent long distance lines in Southern and Western Minnesota, Northern Iowa and South Dakota, including the Minnesota Central Company, which recently secured a franchise in St. Paul. The lines included are the Western Electric system, the Western Electric Telephone Company, the Minnesota Mutual Telephone Company and all their dependent and allied companies, which include the Southern Minnesota and Southern Dakota Telephone companies, the Union Electric Telephone Company, the Minnesota Central Company, and Western Minnesota Telephone Company. The parties to the agreement agree that their long distance lines shall hereafter operate in harmony and in direct connection. They will be interconnected so that any town in the territory of any company which is a party to the agreement can get direct telephone connection with any other town on any of the wires of the allied companies. The new deal goes into effect to-day. All the parties to the agreement are bound not to have any business relations with other companies, thus preventing outsiders from making any sort of connection with them."

Referring to this coup of the telephone monopoly the Boston *News Bureau* says:

"We understand that the purchase price of the 900 miles of independent telephone line in the Northwest by the Erie Telephone Company was $50,000. [The Northwestern Company is controlled by the Erie.]

"Boston people do not realize the importance of the above purchase to the Erie Telephone Company. The independent telephone movement in the Northwest had assumed large proportions. There were five companies in the field with a capitalization of $30,000, all under the management of the Western Electric Telephone Company. These companies owned 3,000 miles of toll line in the Northwest, practically embracing the entire toll line opposition in the States of Minnesota, Iowa and the Dakotas, and reached 300 points not reached by the Erie Company.

"The Erie Company purchase was of the lines of the Union Electric Telephone Company, which is the only independent company paralleling the Erie Company's lines, but as a result of this purchase the Erie Company agrees to place Bell instruments on all the Western Electric Company's lines at a small rental which includes the cost of repairs, and both systems will be operated as one.

"This is declared to be the first instance where a Bell company has ever entered into an extensive arrangement with an independent company; the previous policy has been to ignore or fight the independents. In this case there is no transfer of stock, other than of the Union Company, and the independent companies maintain their separate existence and build and maintain their own lines.

"This purchase is considered of great advantage to the Erie Company as it practically cuts off the new Minneapolis independent telephone exchange from all toll connections, for undoubtedly in connection with the Western Electric Company's lines the Minneapolis company would have been able to make inroads on the Erie Company's business. This agreement likewise cuts off a number of other independent exchanges in various cities, as under the agreement only toll lines are embraced, and it prohibits any affiliation with lines other than those using Bell instruments."

The Poughkeepsie *Eagle* states that a large force of men is at work at Fishkill Landing putting up poles and wires for a long distance telephone to connect Fishkill, Newburg and Peekskill directly with New York City. This work is being done by the American Telegraph & Telephone Company for the Hudson River Telephone Company. The new cable across the river at Newburg is for this line. Heretofore the crossing of the river has been made by the cable at New Hamburg.

The construction of the new Standard telephone exchange at Atlanta, Ga., is nearing completion. The underground conduits will be finished in about three weeks. The officials of the company state that 1,000 'phones would be in operation by January 1 and over 3,000 in a few weeks after that. The Standard company is offering 'phones at much lower rates than the Bell, but it is expected that the Bell company will meet these rates, and perhaps cut under them when the Standard people begin operations.

The Michigan Bell Telephone Company has won its suit against the city of St. Joseph, Mich. The decision gives the company the right to erect poles in certain streets which the council refused.

A special to the St. Paul *Dispatch* from Park Rapids, Minn., states that Moody & Kerlin will soon begin the construction of a telephone line from Park Rapids, via Hubbard and Latona, to Mehnaga.

Association of Fire and Police Telegraph Superintendents and Municipal Electricians.

Chairman Ellett of the Executive Committee of the Association of Fire and Police Telegraph Superintendents and Municipal Electricians has issued a call for a meeting of his committee for October 8 and 9, at Wilmington, Del., the home of the President of the Association, Mr. John W. Aydon. The following gentlemen compose the committee:

W. Y. Ellett, Supt. Fire Telegraph, Elmira, N. Y., Chairman.

M. W. Mead, City Electrician, Pittsburg, Pa.

Capt. William Brophy, Chief Electrician Wire Inspection Department, Boston, Mass.

W. H. Thompson, City Electrician, Richmond, Va.

F. C. Mason, Supt. Police Telegraph, Brooklyn, N. Y.

The committee at this meeting will revise the By-laws of the Association and decide upon matters pertaining to the next regular meeting of the Association, which will be held at Wilmington, Del., September 5, 1899. All members of the Association are invited to be present at this meeting of the Executive Committee on October 8 and 9, President Aydon having arranged to entertain all who can make it convenient to do so.

Applications for membership will also be received and acted upon at this session.

A practical test of the Canadian Pacific's new copper wire was made on Wednesday last between Montreal and Vancouver, and the time consumed in sending a message to Montreal and transmitting reply to Vancouver was about a minute. The wire was duplexed, being made capable of carrying two messages in the opposite directions. The actual distance covered by this new wire is about 2,900 miles, constituting probably the longest direct land line circuit for daily work in the world. To pass across this immense distance signals only occupy one-fifth of a second. This direct current will enable Montreal, Vancouver, Winnipeg, Rossland, Nelson and other far Western points to transact speculative business between these points almost as quickly as between Montreal and Chicago. The alternative telegraph line to the Kootenay via the Crow's Nest Pass line, will also be completed this fall.

At Chattanooga, Tenn., an ordinance introduced in the council to extend the franchise granted to J. A. Helvin for a new telephone system, which expired September 7, was referred to a special committee consisting of Aldermen McMahon, Martin, Glover, Forstner and Hill.

The long distance telephone line between Portland, Ore., and San Francisco is nearly completed. There is a gap of forty miles only between Grant's Pass and Oakland, Ore., remaining to be wired, and 100 men are now at work on this section.

Consul Roosevelt at Brussels writes that work is soon to be begun on a telephone line between Berlin, Brussels and Paris. When completed, the line will be more than 620 miles long, and therefore the most important telephone line in Europe.

New Companies Incorporated.

At Jefferson City, Mo., the Atlanta Telephone Company of Atlanta, Macon county, Mo. Capital stock, $2,700. Incorporators: H. H. Abbott, S. H. Nash, R. B. Turner and others.

At Trenton, N. J., the Atlantic Telephone Company. Capital stock authorized, $100,000. Incorporators: Frederick L. Benson, Alfred Dingler, Jersey City; John J. McCloskey, Philadelphia.

The Postal Telegraph Cable Company, Des Moines, Ia.—to construct, acquire and operate telegraph lines within the State of Iowa. Capital stock, $50,000. Incorporators: C. F. Fox, R. J. Wurst and R. W. Banks.

The Ottumwa Long Distance Telephone Company, Ottumwa, Ia.—to build long distance telephone lines in the States of Iowa and Missouri. Capital stock, $10,000. Incorporators: J. C. Goddard, A. H. Cowdery and P. E. Wilcox.

The Morgantown & Dellslow Telephone Company, Morgantown, W. Va. Capital stock, $100,000; subscribed, $500; paid in, $50.

The Luraville & Suwanee River Telephone Company, Luraville, Fla.—to construct and operate a telephone system. Capital stock, $3,000. Incorporators: Thomas I. McIntosh of Luraville, Sidney V. Hough of Lancaster, Fla., L. T. Boatright of Live Oak, Fla., William T. Dees of Mayo, Fla.

The Meridian Telephone Company, Meridian, Miss. Capital stock, $16,000. Incorporators: J. D. P. Lewis, J. P. Walker, Henry A. Coit, Henry A. Turner and others.

The Greenbrier & Pocahontas Telephone Company, Ronceverte, W. Va. Capital stock, $1,500.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12⅛c.; Lake, 12¼@12⅜c.; casting, 11⅞@12c.

The new underground trolley cars on the Sixth Avenue line, New York, began running on the 1st inst.

Application has been made to the New York Stock Exchange to list $2,000,000 additional capital stock of the Third Avenue Railway.

The regular quarterly dividend of 1¼ per cent. was declared payable October 1 by the directors of the Cincinnati Street Railway Company.

The North Chicago Street Railway Company has declared a dividend of 3 per cent., payable October 15. Books close October 5 and reopen October 15.

The Central & South American Telegraph Company has declared a regular quarterly dividend of 1½ per cent., payable October 8. Books reopen October 10.

The New York & New Jersey Telephone Company has declared a regular quarterly dividend of 1½ per cent., payable October 15 to stockholders of record October 5.

The Metropolitan Street Railway Company, New York, has given notice that it will pay its debenture certificates on or before October 15 at the office of the company, 621 Broadway.

It is stated, says the Philadelphia "Times," that the Pennsylvania Manufacturing, Light & Power Company now controls every local lighting corporation in Philadelphia except the Southern Company.

The president and promoter of the new Porto Rico Cable Company arrived in New York on Thursday last from San Juan and is staying at the Imperial Hotel. He will establish headquarters in the neighborhood of the hotel.

Two-thirds of the stockholders of the Rapid Transit Railroad Company of Syracuse, N. Y., have consented to placing a secondary mortgage of $500,000 on the company's property, the money to be expended in improving the lines.

The Electrical Exchange, which since November, 1896, has been engaged in the sale of electrical apparatus and supplies at 174 South Clinton street, Chicago, made an assignment on the 22d ult. to L. O. Gilman, Chicago. The assets and liabilities of the company are estimated at $12,000 each.

A majority of the stockholders of the electric light company at Wilkes-Barre, Pa., on the 30th ult. voted to sell out their holdings to men who control the Consolidated Gas Company. A State law prohibits consolidation, but it is said the companies will work in harmony.

The governing committee of the New York Stock Exchange on the 28th ult. listed the Westinghouse Electric & Manufacturing Company's additional issue of assenting stock, $575,000, making the total amount listed $8,813,000. This stock is issued in part payment for the securities of the Walker Company.

Application has been made to the governors of the New York Stock Exchange to list the following Brooklyn securities: Brooklyn Rapid Transit $227,000 additional mortgage 5 per cent. gold bonds; Brooklyn Heights Railroad $2,225,000 consolidated mortgage 5 per cent. guaranteed gold bonds of the Brooklyn, Queens County & Suburban Railroad.

The N. Y. "News Bureau" says that while the officials of the Brooklyn Rapid Transit Company refuse to give any details concerning the deal with the Nassau Company, they admit that the control of the latter has been obtained, and that all the details will be arranged within two or three weeks. An official estimates that the operation of the two systems under one management will result in a saving of $1,000,000 per year.

The Diamond Electric Company, which has a factory at Peoria, Ill., and offices in the Fisher Building, Chicago, has made an assignment for the benefit of its creditors to David H. Robbin, Chicago. The assignment was precipitated, it is said, by the entering in the United States Court on the 27th ult. of a judgment of $10,760 against the Diamond Electric Company in favor of the John A. Roebling's Sons Company.

A mortgage for $1,000,000 was recorded in the office of the County Register at Newark, N. J., on the 23d ult. It was given by the State Telephone Company of Jersey City to the Fidelity Trust Company of Newark. The mortgage is signed by W. I. Taylor, president, and W. C. Cox, secretary of the State Telephone Company, and by Jerome Taylor, second vice-president, and Uzal McCarter, secretary of the Fidelity Trust Company.

The Edison Electric Illuminating Company of Brooklyn has declared an extra dividend of the entire amount standing to the credit of profit and loss on June 30, 1898, together with the insurance reserve, and deducting therefrom expenses incurred through the proposed issue of $10,000,000 first consolidated bonds and its purchase of the stock of the Municipal Company. Holders of the stock of September 30, 1898, and the new stock of the company will participate in this dividend, which will be paid as soon as the accounts of the company are made up. In July, when this dividend was first publicly mentioned, it was said that it would amount to about 3 per cent. on the outstanding stock.

A syndicate of Southern Pacific Railroad capitalists of which H. E. Huntington is at the head has obtained control by purchase of the Los Angeles Railway Company's property, which includes practically all the street railways in Los Angeles. The details of the transaction involve the issue of $5,000,000 in bonds by the new corporation. Of this amount $4,000,000 is to be devoted to cancelling the $3,000,000 bond issue of the old corporation, to the discharge of a floating indebtedness of $400,000 and to certain improvements to be made in the property. The bonds of the new company are to bear 5 per cent. interest. The price paid for the property of the old company is said to have been $3,900,000.

The trust deed of the Chicago & Milwaukee Electric Railway has been filed and it provides for a total issue of $1,000,000 5 per cent. gold bonds, maturing in twenty years. The Illinois Trust & Savings Bank is the trustee. Of the authorized issue, $400,000 are to be certified and delivered at once, while the remaining $600,000 can be issued only to cover 75 % of the cost of future extensions and improvements. The line has been in operation from Waukegan to Highland Park, a distance of about 18 miles, since July 1, and it is on account of this portion of the system, including private right of way, power house and equipment, that the $400,000 bonds are issued. It is stated that over $500,000 has been expended on the road as it stands.

A report has been prevalent during the week that ex-Governor R. P. Flower is seeking to gain control of the electrical interests along the Hudson River from New York to Albany with the idea of making a complete trolley line between Albany and the metropolis. Should such a project be consummated there will be trolley connection through as far as Troy and Stillwater, as electric lines already extend between Albany, Troy and Stillwater. The project involves millions of dollars. At Yonkers the street railway interests are in the hands of A. L. Johnson, president of the Nassau system, recently taken up by the Flower interests, and at Poughkeepsie the interests are controlled by J. W. Hinkley, a financial associate of Mr. Flower. The control of the Hudson City Electric Railway, the Hudson City light and power plant and the Kinderhook & Hudson Railway has been secured, and it is proposed to extend the Kinderhook & Hudson line from Niverville to Nassau, a distance of twelve miles. In connection with this project it is reported that the plan is to absorb all of the chief electric lighting companies, with a view to furnishing power and light from the same plants, and thereby cheapen the cost of production.

ELECTRICITY.

Vol. XV. NEW YORK, OCTOBER 12, 1898. No. 14.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY

THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

The New York Gas & Electric Light, Heat & Power Co.

Considerable interest is being taken in the New York Gas & Electric Light, Heat & Power Company, which was incorporated at Albany on October 3, with a capital of $25,000,000, and no one believes that the men whose names appear as the incorporators are in reality the financial backers of the enterprise. As is now generally known, the principal object of this company is the distribution of electricity for use in New York City. It has been rumored, and this rumor is undoubtedly founded on the large amount of the new company's capitalization, that a combination of plants already in operation has been effected or is in prospect. It is also thought by many that the Metropolitan Traction Company is back of the new project, especially now that the latter corporation is preparing to use electricity on most all of its lines. Another incident that would seem to strengthen the belief that the Metropolitan Traction Company is interested in the concern referred to is the fact that a large number of conduits are now being laid as speedily as possible along Broadway, ostensibly to furnish electric power for operating the Broadway line, but apparently of much greater capacity than is required for the car lines. President Vreeland when recently asked whether his company was not laying more conduits than were actually necessary for operating the cars, made the following statement, which appeared in the New York *Sun* :

"We are not. It may seem as if there were more conduits going down than are necessary, but there are not. In the first place, with the underground system it is necessary to have metallic circuits. That is, there must be wires running both ways, instead of only one, as is the case where the overhead trolley is used. It has been found impracticable in underground work to use the rails as a return conductor. This doubles the number of wires. It is expensive, but it is the only thing practicable. Besides, it does away with electrolysis, which in some cities plays such havoc with water and gas pipes.

"According to our plans the entire road, say the Broadway line, is divided into sections, each about 1,500 feet long. Each section is entirely independent of the others, and should it break down would not affect the road as a whole. This guards against long blocks, as the cars, once passed over the broken down section, would run along all right.

"The system is a good one, the only one practicable in a city like New York; but it necessitates the putting down of many wires. We are putting down a good many, but they will all be needed. On the Lenox avenue experimental line were first laid eighteen wires. Soon after we put down eighteen more, and before a great while eighteen more."

The conduits now being put down by the Metropolitan Company adjoining each track along Broadway are three and one-half inches internal diameter and range in number from eighteen to thirty-six. In spite of the above statement, and even granting metallic circuits are used throughout, from a rough calculation we have made it is difficult to see how, even under the most trying conditions, thirty-six conduits should be necessary.

As we understand it, the Metropolitan Traction Company proposes to generate the necessary power for operating its lines at its new power house now building at Ninety-sixth street and First avenue. This station will have a capacity of 90,000 horse-power and an alternating high tension distribution system will be employed. It has been claimed by some that the Metropolitan Traction Company is not in a position to dispose of current for power purposes even if it wished to, as it will require from 75,000 to 80,000 horse-power to operate the cars on its various lines, and that the difference between that and 90,000 will be needed for lighting purposes, etc. Even granting such to be the case, we do not see as this would prevent the Metropolitan Company from generating power at its present cable power houses at Houston street, Fiftieth street and elsewhere, and disposing of it to private consumers if it so desired. According to President Vreeland's statement, fifty-four conductors are ample to operate the Lenox Avenue line, and yet along Broadway there are at present being laid seventy ducts, each capable of holding at least one cable. With high tension transmission, moreover, the number of cables should be materially reduced as much less copper would be required than if a direct-current system of distribution were employed. A well-known builder of electric subways recently made the following statement, which appeared in the paper already quoted :

"Any novice can see that it would be a profitable venture for the Metropolitan to lay down a few ducts for rental. The standard rental for subways is $1,000 a mile per duct, and at this figure the Metropolitan could pay for its subway in a year if it rented it all, for a thirty-duct subway would bring $30,000 a year rental for every mile. In some sections there will be forty ducts, and in others many less. One can easily understand what a profitable arrangement it would be for a new light and power company to unite with the Metropolitan. Are they going to? That I can't say. I am in a position where I can't talk about this matter. All I can say is that the Metropolitan is laying a great many ducts."

Taking it all in all, we are rather inclined to be-

lieve that the Traction Company is in some way interested in the New York Gas & Electric Light, Heat & Power Company—if not, and if all the conduits now being laid along Broadway are necessary for operating that line, underground traction in New York City is decidedly an expensive luxury.

* * *

Lighting from Car Axles.

Since the general adoption of electricity for illuminating purposes, various attempts have been made to introduce this form of illuminant in railway trains. One means adopted for this purpose consisted in placing a generating set in the baggage car of a train and running it by steam taken from the locomotive. This necessitated coupling all the cars to be lighted by electricity in a train together by means of an electrical conductor. If for any reason it became necessary to detach a car from the train, in order, for instance, to switch it onto a different route, the lights in that car would immediately be extinguished. Some of the New York dailies have recently taken up this question of electric train lighting, and one of them after dwelling on the disadvantages of the baggage car dynamo system says:

"But now a new idea, simple but seemingly effective, has been put forward. It is to have a separate dynamo for each car, to be operated by a cog-chain run on a wheel attached to the axle of the car. The electricity is conducted to storage batteries and from them diffused throughout the car. Each car is then separate and independent in its lighting. Enough electricity is generated in a run of 150 miles to light the car during the trip and for six hours afterward. In daylight the current is used to operate ventilating fans."

From the way in which some of the dailies have discussed this method of train lighting one might be led to believe that the attaching of a dynamo to the axle of a car with a view to procuring electric current is an entirely new departure and has never been successfully attempted until now. This is however not the case. Three United States postal cars on the Atchison, Topeka & Santa Fe Railway have been equipped with a device of this nature for procuring current for lighting purposes since last March, and these cars are said to have been running regularly ever since between Chicago and Kansas City. Each car is provided with twenty-four 16 candle power lights, which are kept lighted while the car stands in the station by a system of storage batteries located on the car itself. On the first of last April there were fifty-four cars thus equipped running regularly on the Santa Fe system which from all accounts have given entire satisfaction. In the system here used the dynamo is fastened to a cross piece on the truck and operated by means of a belt passing over two different size pulleys. The arrangement of pulleys is such as to keep the speed of the armature of the dynamo as nearly constant as possible. Each car is likewise provided with an extra belt to replace the one in use in the event of its being lost. The replacing of a belt consumes but four minutes. The Pennsylvania Railroad, if we are not mistaken, already has several cars equipped in this manner, and the New York Central has one or more cars lighted from the axle. The idea of utilizing current generated from a car axle is therefore by no means new even on steam railroads, and the principle has frequently been made use of in trolley systems. In some street railway systems where a steep grade is encountered the motors on the cars have been made to act as generators and feed back current to the line. A novel idea would be to make use in some way of the enormous amount of energy lost in the frequent application of the brakes to the wheels on a railroad train. It might be possible to utilize at least a portion of this wasted energy in driving a small dynamo at each application of the brake shoe against the rim of the wheel. This is offered merely as a suggestion and as food for thought.

The New Battleship Illinois.

At Newport News, Va., on October 4, in the presence of thirty-five thousand people, the first-class battle-ship Illinois was launched. This ship, which was contracted for, together with the Alabama and Wisconsin, in 1896, will have when fully equipped a displacement of 11,525 tons, or 185 tons greater displacement than the Iowa and 1,225 tons greater than the Oregon. The armor of the forward conning tower will be ten inches in thickness. The tower itself will be oval in shape, seven by eleven feet in the clear, with a heavily armored tube seven inches in thickness extending down to the protective deck for the protection of the electrical conductors used in signaling. In all there will be about eighty auxiliary engines in the vessel for operating cranes, deck winches, pumps, windlass, steering gear, etc. The propelling power will be derived from two sets of triple expansion twin screw engines of 10,000 collective indicated horse power, each located in its own separate water-tight compartment. The steam necessary to operate these engines will be derived from eight cylindrical boilers. The latter will be connected in batteries of two each, each battery being located in a water-tight compartment. By this arrangement the chances of the vessel ever becoming entirely helpless are reduced to a minimum.

The electrical equipment of the Illinois will be most complete and thorough. There will be eight generating sets for supplying the enormous amount of current required in operating the searchlights, of which there will be four, ventilating fans, signal bells, incandescent lamps for ordinary illuminating purposes, bulkhead lamps, cargo reflectors and night signals. There will be but one main switchboard, from which the battle and lighting circuits will radiate. As already in the case of several of our naval vessels, the ammunition hoists on the Illinois will be operated by electricity, thus doing away with considerable cumbersome machinery. That the use of electricity as a motive power for heavy work on the new vessels of the United States Navy is increasing, slowly it is true but nevertheless surely, cannot be doubted, in spite of the opposition to this form of motive power by the advocates of steam and compressed air. As we pointed out in an editorial last week, the adoption of electricity on fighting ships has many advantages to recommend it, and as more care and pains are taken in the design of special electrical apparatus for use on shipboard, the number of installations will undoubtedly increase until every piece of machinery will be operated by this power, excepting of course the main propelling engines.

Under the Searchlight.

Notes and Comments on Various Topics.

THE news is being passed around that the Westinghouse Company has been awarded the contract for equipping a woolen mill at Tientsin, China, with electrical machinery. This is a new departure, and a great deal less repulsive than putting electrical equipments into the Parisian and Roman catacombs, or even setting up a dynamo in the Pyramid of Cheops.

* * *

SIR ELLIS ASHMEAD-BARTLETT's special pleading for Turkey at the time of the Armenian massacres and his eccentric conduct during the war with Greece, which subjected him to much ridicule, may after all result not only to his own advantage but also in breaking down some of the prejudice against modern innovations that is keeping Turkey in the background. He has been granted by the Porte concessions for electric lighting and traction in Smyrna and Salonica, and priority of right is promised him also in Constantinople whenever the Sultan makes up his mind to allow the use of electricity in his capital. Sir Ellis Ashmead-Bartlett, an American by birth, is an English M. P., and married the Baroness Burdett-Coutts.

* * *

A PROFESSIONAL school of electricity is to be established near Paris, France. The school is intended to furnish laborers and foremen with an electrical education, and first-class instruction will be given in both theory and practice.

* * *

FROM all accounts Emperor William of Germany does not intend to allow himself to be assassinated if he can prevent it, and with this object in view is said to cause the guards on duty at the imperial palace to carry telephone transmitters whereby warning may be sent of the approach of suspicious persons.

* * *

ANOTHER opportunity for inventive genius to display itself is presented by the Society for the Encouragement of National Industry, Paris, in its offer of various prizes to be awarded during the coming year. Among these is a prize of $600 in connection with the manufacture of permanent magnets; research in this case may be directed to the composition of the steel for the magnets and such materials other than iron which may enter into it, or to the degrees of temperature for the liquids used in tempering; also the processes of annealing and other necessary accessory operations which are likely to obtain this result. Another prize likely to call forth considerable effort is for an incandescent electric light, one not to exceed a maximum of two candle power—decimal system. Four hundred dollars are also offered for any set of electrical appliances or tools suited to domestic life and to small trade.

* * *

AN electric fan which had been put into the dining-room of a Washington residence was, the *Star* states, a matter of great interest to the colored attachés of the household :

One of them, a stout "auntie," stopped and gasped ostentatiously every time she passed before it.

"Whut de matter, Aunt Hannah?" asked the boy who was supposed to help around the kitchen and who was her especial aversion. "What makes you keep shyin' like a hoss?"

She disdained to answer, but chancing to pass the fan again, gave another gasp.

"Is you got de ast'ma, or is you jes' pantin' 'cause it's a wahm?"

"Sonny," she responded slowly, "I desires to ax you sumpin'. Is you fishin' foh trouble? Case if you is, you wants ter watch your cork. You's got a bite right now."

"No'ndeed. I isn' lookin' foh trouble. I was only 'quirin' aftuh yoh health an' comfort. I wanted to make sho' whether yoh wus a-skyaht o' dat fan."

"Me a skyaht o' dat?" she exclaimed with great contempt. "I's humiliated. Dat's whut I is. An' I guess dey is mo' service places dan dis, so's I won' hafter quit workin' when I's left."

"Is yoh gwine away?"

"I is."

"Whut's yoh dissatisfaction?"

"Laziness. White folks' laziness. I doesn' speck quality folks to wuck hahd. But dah's sech a thing as kyahyin' luxury an' ease too far for respectability. I doesn't blame 'em foh gettin' red o' de cookin' an' cleanin' an' passin' de dishes at dinner. But when dey gits so dey's got ter set up machinery to help 'em draw deir bref, I tells you, chile, dey's got clean past de limits ob gentility."

* * *

THE *Lady's Pictorial* describes an electrically propelled baby carriage, regarding which *Electricity* of London comments as follows: "It is intended that the nursemaid shall control the pace of this vehicle when the occupants are of specially tender years, but in time babies of due discretion will be entrusted with the management of their own perambulators. It would be difficult perhaps to devise a more effective training in the duties of citizenship and self-

government for the rising generation, but we old fogies will probably have an exceedingly lively time of it meanwhile; and to some of us it may seem that progress and the Zeitgeist are making undue demands upon our forbearance when we have our toes run over and ourselves knocked sideways by the emancipated babies. But we shall bear it with patience, I doubt not, in the sacred cause of Humanity—with a big H."

* * *

AN electric grate has recently been brought out The grate standing in a fireplace in the usual manner has within it an incandescent lamp over which is placed a wire cage at such a height in the grate that the imitation coal, composed of ruby and amber glass, when spread over it is brought up to the height of an ordinary coal fire. About as much heat is derived from this grate as from Mark Twain's stove with a candle in it. It therefore serves as an ornament for imaginative people.

* * *

Having Fun With their Electric Lights.

Some California towns are in a state of chronic irritation over their electric light service, and this is scarcely to be wondered at if the facetious comments the local papers print in regard to it are founded on facts and are not the figments of editorial fancy. The following appears in the Riverside *Enterprise* of a recent date:

The quality of the electric light service furnished by the San Bernardino people must belong to the same tribe of that supplied here, for the *Times-Index* says:

"The situation in regard to the city lighting seems to be growing worse and worse in place of better. The 10 years contract made with the San Bernardino Electric Light Company has yet nine years and several months to run, and at the present rate of illuminative attenuation, it is believed the darkness will become fully as dense as that of the Cimmerian desert long before the contract has expired. The charge is $6 50 a month for each dark light, and there are supposed to be 63 of these dark lights, although not more than one-half of them make even a painful and impotent stagger to shed the ghastly gloom for which they were put up."

The *Times Index* is too exacting. It grieves that only 30 out of 63 street lights burn. The rate of percentage would be considered a big thing in this city, where not a single street lamp out of 85 has done any shining for many moons, yet the taxpayers here paid $50,000 for their alleged system of street lights.

It seems, however, that the San Bernardino city trustees took some action in regard to the failure of the lights, for here is the *Times-Index's* record of the proceedings:

"And that grewsome, globular, nocturnal effulgence which casts spasmodic shadows on Court street is a particularly expensive luxury. It is of 2,000 flicker power, and at so much per flicker—well, it is something of a tax-consuming monster. When the matter was brought before the Cimmerian oligarchy, the latter just smiled and said: 'The public be ——! Let 'er flicker!'"

Here in Riverside no notice whatever in an official way has been taken by the trustees of the failure of the Redlands Company to fill its contract, a contract which it gave a bond to carry out. The city dads did not even think it worth while to make a statement to the taxpayers, as the San Bernardino trustees did, as recorded above.

The reputation of the light service of this city has even reached the sanctum of the Santa Ana *Blade*, for McPhee, n a late issue of his paper, expresses his opinion as follows:

"We just hate to exult over the troubles of any community, but in view of the manner in which the electric lighting plant of Riverside was held up to our people as the greatest and best thing on earth and a wonderful proof of the advantage of municipal ownership, we are tempted to say 'I told you so.' The great municipal ownership scheme for lighting the city of Riverside has turned out to be anything but a success. During the day Riverside is as well lighted as any place in the country, but at night—that's different."

Electric Sterilization of Water.

The water taken from the Bruges Canal at Schoorebrugge is first filtered in the usual manner through beds of different kinds of sand, and is finally pumped through sterilizers, being there subjected to the influence of an electric current at a pressure of 1,000 volts. It is stated that by this means all traces of microbes are entirely destroyed, and the pure water is distributed to the inhabitants of Blankenberge by means of the system previously in use. About 35,000 cubic feet are treated per day in summer, this value falling to about 10,000 cubic feet per day in winter. The electrical installation has an output of 55 HP.

Light-Electric Telegraphy.

Prof. Zickler of Brünn has conducted an elaborate series of experiments which show that a telegraphic instrument can be actuated at considerable distances by a beam of ultra-violet light. He employs a powerful arc lamp as his transmitter, using a screen of glass to produce intermittent flashes of the ultra-violet beam, which embody themselves as dot and dash signals on his receiver. The receiver is an air-gap in a circuit containing an induction coil regulated to an EMF. just below the sparking point at the air-gap. As Hertz long ago has shown, a beam of ultra-violet light falling on the cathode of a strained air-gap, near its breaking down point, will immediately provoke a discharge. Zickler started by producing this effect over a distance of 2 m. Then, by improving the shape and material of his electrodes and enclosing them in a chamber of compressed air, he was able to increase this distance to 200 m. This is a remarkable result, and it is extremely interesting to physicists to learn that the short and easily absorbed ultra violet light can influence a spark discharge at so great a distance; but to think of this as a practical system of wireless telegraphy, as Prof. Zickler appears to do, is a *reductio ad absurdum*. The light within the limits of the visible spectrum which an arc emits will do all the signaling that the ultra-violet beam is capable of, will penetrate to much greater distances and can be manipulated with much simpler apparatus. The ether waves of the visible spectrum which Nature has successfully used for signaling since the creation are in danger of being rejected for our new ones, ultra-violet or Hertzian waves, which Nature probably long ago tried and found wanting.—*Electrical Review, London.*

THE JUNGFRAU RAILWAY.*

The first section of the electric railway up the Jungfrau was opened Sept. 19. We had the good fortune to inspect the line a few weeks ago, and we make use of this opportunity to publish a description of it.

The Jungfrau is one of the highest of the Swiss mountains, its summit being 13,670 ft. above sea-level. It is the highest of the group Eiger, Mönch and Jungfrau, which is considered by some to be the most beautiful of the Swiss snow mountains. The grandeur of the glacier region which surrounds it, and the magnificent panorama that can be obtained from the summit, have made the Jungfrau a favorite among mountaineers, but to ascend it a night has to be spent on the mountain and it must be reckoned among the big climbs of the Alps. Having already referred from time to time to the inception and progress of the project for building this railway, a

FIG. 1.—VIEW OF THE JUNGFRAU FROM THE LITTLE SCHEIDEGG STATION.

scheme which was originated by Herr Guyer Zeller, president of the Jungfrau Railway Commission, we will now confine ourselves to a description of the line itself and the works in connection with it.

Fig. 1 is a view of the mountain from the Little Scheidegg station of the Wengern Alp Railway. The Wengern Alp Railway is a rack and pinion railway driven by steam locomotives. It starts from Lauterbrunnen and ascends the Wengern Alp to the Little Scheidegg (an elevation of 6,770 ft. above sea-level), from whence it descends on the other side of the mountain to Grindelwald. The Jungfrau electric railway starts from the Little Scheidegg station of the Wengern Alp Railway and ascends the Jungfrau from the north side. It may be mentioned incidentally that tourists have nearly always climbed the Jungfrau from the south side as the route from the Little Scheidegg is very hazardous for pedestrains. Fig. 2 is a perspective sketch of the Eiger, Mönch and Jungfrau showing the direction of the existing Wengern Alp Railway in a dotted line, the first section of the Jungfrau railway from the Little Scheidegg to the Eiger Glacier station as a full line, and the remainder of the railway, which is

* From the *Electrician*, London, Sept. 23.

under construction, dotted. A table of the projected stations, with elevations, distances and gradients, is given below.

On the section of the line already opened there is only a distance of about 85 yards in tunnel, but from the Eiger Glacier onwards the railway will not touch the surface except at the stations. Almost immediately after leaving the Little Scheidegg station the gradient is 10 per cent., and this is increased to 20 per cent. at about half-way to the Eiger Glacier station. From this station the gradient increases to the maximum of 25 per cent. and the line enters the long tunnel, about 450 yards of which has been driven up to the present. The remaining stations from Eiger Wand onwards will be built within the rock, and it is intended to fit them with restaurants and sleeping accommodation for those passengers who may wish to break the journey. From the Eiger Wand and Eismeer stations there will be no egress on to the mountain, and tourists will merely be able to enjoy the view from windows or balconies, but from the Jungfraujoch station it will be possible to go out on to the Jungfraufirn and sledge over the perpetual snowfield to the Aletsch Glacier. It is expected that this station will be made use of to a considerable extent as a starting place for tours. It had been originally intended to have an open station on the Mönchjoch (with possibly a branch line to the summit of the Mönch) which would have been situated between the Eismeer and Jungfraujoch stations, but at a higher level than either. This was, however, abandoned on consideration. Had there been a failure of current after a train had passed this station it would have been impossible for it to descend to the Little Scheidegg merely by using the brakes, and the train would be delayed in the mountain until the interruption of supply was made good. According to the present scheme there is no change in the sign of the gradient, and passengers would be able to return to the starting point if there were a breakdown of the line or in the power-house.

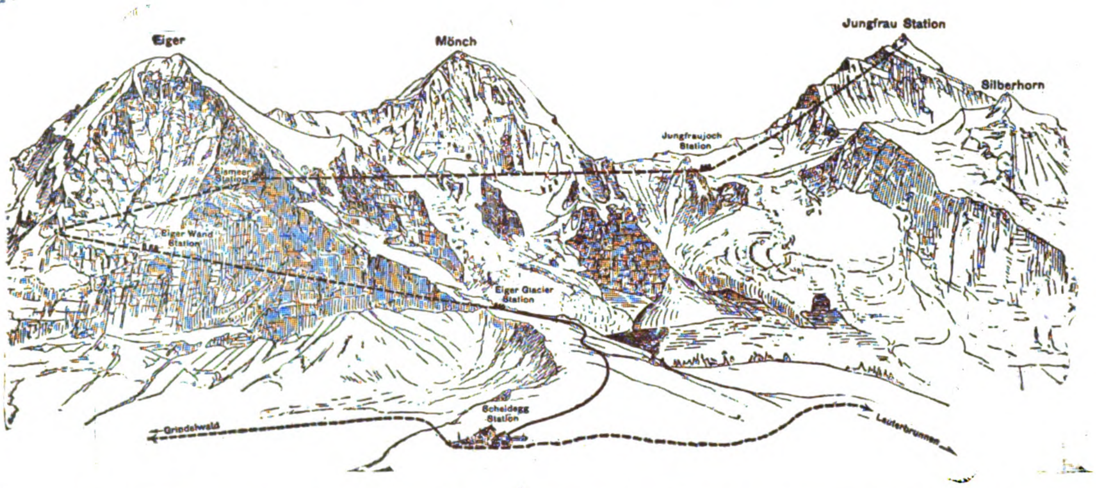

FIG. 2.—SKETCH OF THE JUNGFRAU GROUP, SHOWING THE ROUTE TO BE TAKEN BY THE RAILWAY.

The Jungfrau line is one of the most interesting applications of three-phase transmission and distribution yet made. Water-power is made use of in the valley to generate three-phase current at 7,000 volts, and this is transmitted by means of overhead wires to transformer stations at the Little Scheidegg and the Eiger Glacier where it is transformed to 500 volts by means of stationary transformers. Not only is electrical energy employed for traction purposes but also for lighting, heating and for working the rock drills used in the tunnels. When the railway reaches a certain altitude, the energy expended in heating the trains and stations will be an important item of the total cost.

At present only one power-house has been built, this one being situated on the White Lütschine, near Lauterbrunnen, right down in the valley. The power transmission line from Lauterbrunnen to the Little Scheidegg is about $4\frac{1}{2}$ miles long. The ascent of this $4\frac{1}{2}$ miles by foot takes about three hours—an hour and a half by the rack and pinion railway—the difference in level being about 4,250 feet. The three wires are of bare hard-drawn copper wire 7.5 mm. diameter. They are supported on large earthenware three-lipped insulators of about $4\frac{1}{2}$ in. diameter and 7 in. high. Stout wooden poles, about 33 ft. long, are used, with galvanized iron brackets. Wherever the wires cross a footpath they are nearly surrounded by a circular guard-net of very wide mesh, intended to prevent a wire from falling to the ground in case of breakage. A metallic circuit telephone line is fixed on the same poles, some distance below the three-phase wires, and the two telephone wires are crossed every 550 yards to prevent induction effect. As a matter of fact, this proves to be insufficient protection from induction noise, and it will be necessary to cross the wires more frequently. Lightning protectors of the Siemens & Halske horn-shaped pattern are used on each of the power wires and at each end of them, and similar lightning protectors are applied to the secondary wires. The fall of potential will be about 10 per cent. at full load.

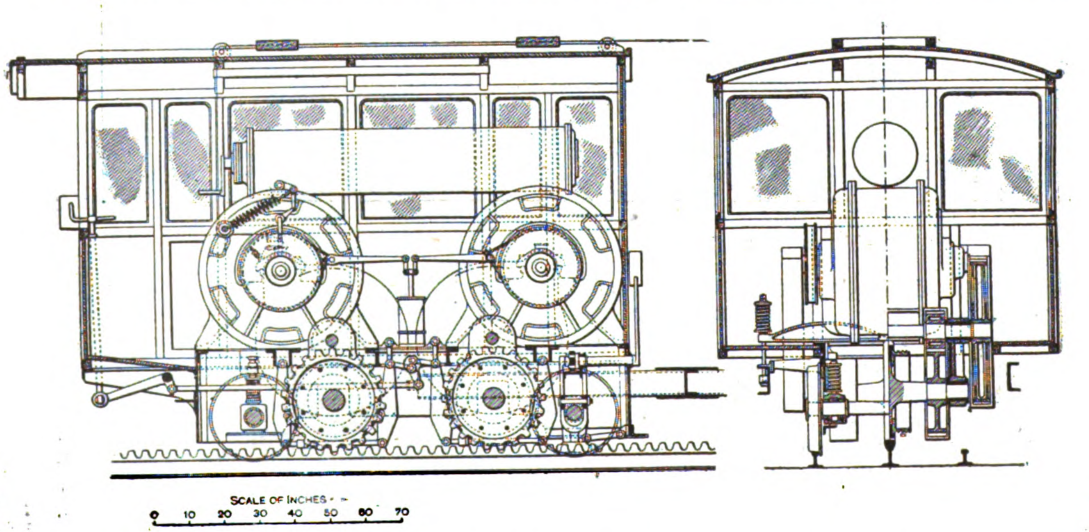

FIG. 3.—ELEVATION AND SECTION OF LOCOMOTIVE, SHOWING GEAR.

The transmission line is not duplicated, so that if it were interrupted all power would be cut off from the railway. A duplicate power station is projected however at Burglauenen, near Grindelwald, on the other side of the Wengernalp, capable of supplying some 2,600 HP., which is to be furnished by the Black Lütschine. This will feed the Little Scheidegg transformer station through a quite independent transmission line of similar construction.

The sub-stations are substantial stone buildings, designed to withstand the action of the most inclement weather. They are each fitted with two 200-kilowatt transformers, reducing the pressure to somewhat over 500 volts for the secondary feeders. The latter are of 9 mm. hard-drawn copper and are constructed in a similar manner to the transmission line. The transformers are built by the Oerlikon Co. The fuses are of copper wire outside the sub-stations. In addition there are rotary transformers at the Eiger Glacier station, which supply continuous current for the rock drills and lighting. When more of the line is built, transformers will be added every kilometer (1,094 yards).

The permanent way is built on the Strub rack

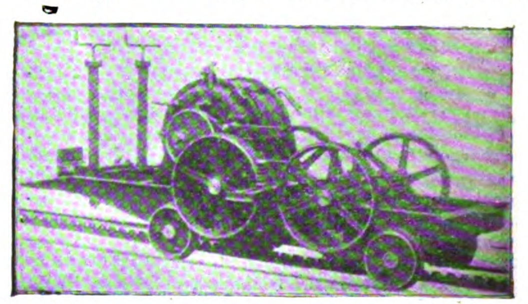

FIG. 4.—LOCOMOTIVE TRUCK.

system. Meter gauge (3 ft. $3\frac{3}{8}$ in.) is employed, the rails being of the usual Vignoles profile, $3\frac{15}{16}$ in. high and weighing 40 lbs. per yard. The length of the sections of rail average 34 ft. 6 in., and steel sleepers are used, their distance apart averaging about 3 ft. 3 in. The rack, which is as usual half way between the rails, is of rolled steel. It is rolled solid and the teeth are cut afterwards in the cold bar. It is made in lengths of 11 ft. 6 in., and weighs only $68\frac{1}{2}$ lbs. per yard. Its mean tensile strength is $28\frac{1}{2}$ tons per sq. in., with an elongation of 20 per cent.; the same clips are used for the rails and rack. The conical shape of the teeth of the rack permits the use of an emergency brake which clutches them on both sides. As has been already mentioned, one section of the projected line will have a gradient of only $6\frac{1}{4}$ per cent., and here it is anticipated that no rack

It is estimated that the railway will be completed by 1904.

will be needed. The sharpest curve of the section of the line now opened has a radius of 33 ft., and the

sharpest curve in the tunnel will have 66 ft. radius. Two Chicago bonds of 7 mm. copper are used for each rail-joint, and the rails are cross-connected every 55 yards with 8 mm. copper.

We give several views of the first locomotive built

for the line. Fig. 3 shows the arrangement of gear; Fig. 4 is the truck with one motor removed; Fig. 5 shows the electrical equipment, and Fig. 6 a view of the line, showing the overhead equipment. The

FIG. 6.—PART OF THE FIRST SECTION OF THE JUNGFRAU RAILWAY.

locomotive contains two 125 to 150 BHP. induction motors driven directly at 760 revolutions per minute by the 500-volt three-phase current with a frequency of 38 cycles per second. The weight of each motor is 2.6 tons, and the locomotive complete weighs 13 tons. The construction of the four-wheel truck and the gear are clearly seen in Figs. 3 and 4, which are self-explanatory. Fig. 7 shows the electrical connections. The great advantage of the three-phase system on such a railway is the simple automatic breaking action of the induction motors. When the locomotive is going down hill the stators of the motors cannot greatly exceed the speed of synchronism. From the plan of connections it is seen that the motors are merely controlled by a reversing switch (through which the stator is connected to the line) and the usual rheostat in the rotor circuit to avoid starting the rotor on a short circuit. The locomotive is fitted with three absolutely independent brakes. The first is an automatic one, electrically controlled. By means of a centrifugal governor, when a speed greater than a certain maximum is reached, the current is automatically switched off from the motors, and at the same time a hand brake is actuated. A dashpot prevents slight momentary increases in speed from putting the brake in action. This brake can also be applied by the guard in the passenger car, who is provided with a switch to switch off the current. The second brake is a hand-brake, which applies bronze shoes to a wheel on the driving axle, and the third, which has been already referred to, is an emergency brake which grips the rack. This brake is also lined with bronze. It can be applied either by the driver or by the guard. There are six incandescent lamps on the locomotive, two in series on each phase, and the passenger car will be lit with fifteen lamps, five between each pair of wires. Two trolleys are employed on each wire on account of the large currents which have to be transmitted to the locomotive.

The passenger cars, which cannot be called trailers, as they are pushed not pulled, are built for 40 passengers. These cars had not yet been delivered when we viewed the line. Each train will usually consist of a locomotive and one car, but at times of exceptional traffic another car will be added. At present only two trains will run, one up and the other down.

Before descending to the power house in the valley it will be of interest to refer briefly to the work which is being done in the great tunnel. At the

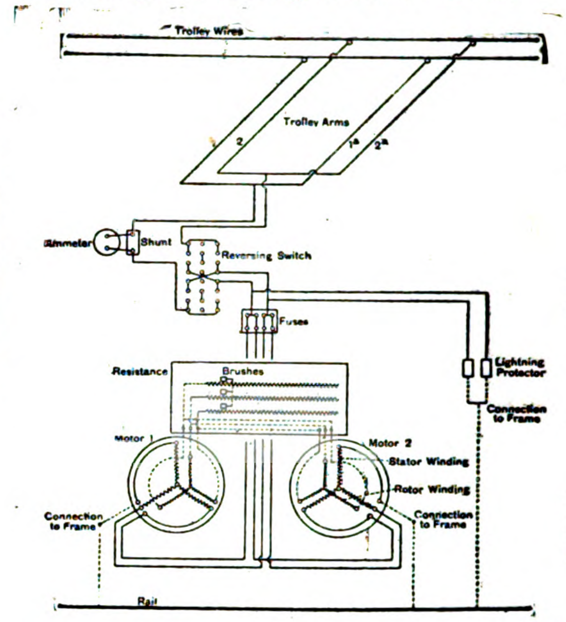

FIG. 7.—CONNECTIONS ON LOCOMOTIVE.

time of our visit 60 workmen were being employed in the tunnel, and 400 in all. Most of the navvies and laborers are Italians. They are provided with food and lodging in barracks built on the mountain for that purpose, and the tunneling work is continued during the winter. As has already been mentioned, electricity is used to work the rock-drills. Both rotary and percussive drills are used. The latter make 400 strokes a minute with $4\frac{3}{4}$ in. stroke. The rotary drills are fitted with 3 HP. motors, and have a self-acting feed of 2 mm. (0.08 in.) per revolution.

(To be continued.)

ELECTRIC MOTORS IN A TANNERY.

A new application of electricity as a motive power has recently been adopted in the tannery of Messrs. Dunn Bros., Cork, Ireland. Of late years, in the early stages of the tanning process, steam power has been largely used to agitate the leather suspended in tanning liquor, the object being to promote the tanning. Various mechanical appliances have been adopted. The American rocker system, so largely used in the United States, has been for years in operation at Messrs. Dunn's tannery, the necessary motion being given by eccentrics on a shaft driven by a steam engine. Each rocker consists of a strong wooden frame at the top of a tanpit supported on pivots and free to move about 6 inches in a see-saw fashion. From this frame the leather to be tanned is suspended in the tanpit, which is filled with tanning liquor. When the frame rocks the leather is gently agitated in the liquor. Experience proves that the best results are obtained with an intermittent motion.

With the usual arrangement, it is necessary that the starting and stopping should be done by some one on duty for that purpose, and consequently the intermittent motion cannot be continued during the night without considerable extra expense. In the new arrangement, electricity developed by a dynamo driven by a steam engine, is stored in accumulators. A clock turns a commutator, which at intervals switches on a weak current that works a relay which

switches on the full power of the accumulators to a motor which rotates the shaft moving the rockers. The commutator being connected with the minute hand of the clock turns on the electricity for some minutes every hour during the day and night. In this manner alternate motion and rest, found to be so desirable, is automatically produced during the night as well as in the day. In this tannery there are 20 of these rockers, each capable of carrying 50 butts or hides.

The great economy of power obtained by the use of electro-motors is very well exemplified in this instance. The whole set of 20 rockers contained at the time of test about 800 hides or butts worked with 26 volts at the accumulators and a current varying from 14 to 18 amperes, or an average of 410 watts or less than half a unit per hour.

The motor and gearing have been made with special regard to economy in working and possibility of increasing the power if required, by simply adding to the number of cells in the accumulator. Attempts of various kinds have been made to accelerate the tanning of leather by electrical means, some of these systems being electro-chemical modifications of the ordinary process. Dunn Bros.' improvement leaves the tanning process unaltered though expedited. The users of the leather therefore will find it exactly the same as formerly in quality, texture and appearance. It has been an objection to some of the new processes that the resulting product has differed in some of these particulars from the leather to which customers are accustomed, and on which they have found that they can rely.

The machinery in this tannery is of the most modern type. The electrical system of working the rockers now described is the subject of a patent.—*Electrical Review, London.*

ON THE ELECTROLYTIC CORROSION OF WATER AND GAS PIPES BY THE RETURN CURRENTS OF ELECTRIC TRAMWAYS.*

BY DR. J. A. FLEMING, F. R. S.

(Concluded from page 199.)

Let us consider next the electrical conditions in the neighborhood of an electrical overhead system of street railways. In all cases where the uninsulated tram rails are used as a return it is unquestionable that some fraction—perhaps, a large one—of the return electric currents will come back through the earth from the distant or more remote portions of the track to those near the generating station, no matter how well bonded the track may be. The exact distribution of this current flow through the surrounding subsoil it is impossible to determine, but if there is a current at all it involves as a corollary the existence of lines of current flow and orthogonal equipotential surfaces.

We may roughly represent by a diagram the general electrical conditions. Suppose a generating station to be at G and T to be the trolley-line and H G the rails. When cars are in operation, current is being discharged at various places into the line. The end H is at a higher potential than the end G. The Board of Trade regulations permit a maximum of seven volts for this total rail fall. The results will be that through the earth we have a distribution of current flow lines. The terminations of these lines accumulate near places where the cars happen to be, and move with the cars. Orthogonally to these flow lines, or at right angles to them there are equipotential surfaces which are shifting about in the earth as the cars move along. The disposition of the current lines will be modified by the presence of pipes in the ground, in so far as these are conductors, also by the electrolytic counter-electromotive forces.

If, then, subterranean pipes exist in the region occupied by this return flow, and if these pipes have their extremities on different equipotential surfaces, it is certain that current flow must take place through these pipes if they have any longitudinal conductivity, and no amount of conductivity in the soil short of infinite conductivity will altogether prevent this from happening. The proof of this is found in a very simple experiment. In a large vessel containing an electrolyte, say dilute acid, two electrodes are inserted, by means of which a current can be passed through the liquid mass. Two lengths of insulated copper wire have their ends just stripped to lay bare the wire, and are then twisted together to within a couple of inches of the ends. These ends are spread out at right angles. The other extremities are connected to a galvanometer. If the spread out bare ends of this galvanometer wire are dipped in the electrolyte it will be found that a current passes through the galvanometer one way or the other, according to the position of the collecting end. If the spread end is placed so that it is at right angles to the line of the current flow, then no current will flow through the galvanometer. The explanation is, of course, obvious. If the extremities of the exploring wire lie on different equipotential surfaces of the electrolyte when traversed by the current, the galvanometer, of course, indicates a current. If the ends lie on the same equipotential surface, then the galvanometer indicates no current. After the test wire has been employed in this manner it will be found that on stopping the main current the galvanometer gives a transitory reverse current, due to polarization of the electrodes.

In the case of long electric street railways worked on the rail return system it is unquestionable that the difference of potential between the different portions of the track when cars are running involves as a certain consequence the flow of current through the earth, however efficiently the rail bonding may be carried out. Mr. H. F. Parshall has stated (*Proceedings of the Institution of Civil Engineers*, April, 1898) that in tests carried out on an eight-mile track, cutting the rails at the center and inserting an ammeter, showed that 60 per cent. of the current was returning through the earth itself.

I think it will be agreed that it is exceedingly important, in the interests of other industries besides the electric traction industry, that in those cases where this earth flow occurs we should endeavor to find out where this current is going and what it is doing.

It is a matter of great difficulty to carry out experiments on actual electric street railway lines. We cannot always be cutting rails, and we certainly cannot cut gas and water pipes to ascertain the currents which may be flowing in them. I have, therefore, directed my attention to making a sort of working model of an electric traction system with an earth return, and of such a kind that pipes or equivalent conductors can be buried in desired positions, and an electrical survey made of the whole arrangement.

The model is made as follows: A large wooden box is provided, best made of paraffined or well-varnished deal. This box may be any desired size, but is best made square and of a depth equal to half the length or breadth. This box is filled with sea sand or river sand mixed with a little salt to give better conductivity and so compensate for limited dimensions, and the whole mass is moistened with water until it is thoroughly and uniformly damp but without free water on it. The resistance of such a mass will be about 1 ohm per yard cube between opposed surfaces. On the surface of this sand, which represents the earth, conductors can be laid down to imitate an electric tram-line. I have found it convenient to employ rods of plumbago and clay by which the required resistance and current carrying power is obtained. A pair of these rods connected in parallel by platinum wires may be laid down to imitate the line. A fall of potential along the line may be made equal to, say 7 volts, or to the maximum fall permitted by the Board of Trade, by attaching the terminals to a battery of four or five secondary cells to the ends of the line. If an ammeter is included in this line circuit, it will be found that the total current taken is greater when the rods are laid on the damp sand than when they are bodily lifted up. This difference indicates the earth return current. In order to explore the distribution of current through the mass of the "earth," a galvanometer or voltmeter is provided, having flexible leads, and the ends of these attached to two insulated wires twisted together, the other extremities being bared and splayed out to form a sort of fork.

In the sand, then, can be buried, at a slight depth, thin iron or lead wires or tubes, to represent gas and water pipes, and these can be given any required form and arrangement.

An electrical survey can then be made with the voltmeter. If a "pipe" or wire representing a pipe runs nearly parallel to the "line" it will be found that at one end of the line the "line" is positive to the pipe, and at the other that the pipe is positive to the "line." In my own model I have found that the potential differences of such a "pipe" and the line amount to 1 or 2 volts, just as they are found to do in the case of real electric street railways when measurements are made between the rails and a parallel buried pipe.* In the case of the pipes running parallel to equipotential surfaces the potential differences between all parts of the pipe and any one point of the line are nearly the same. By means of the exploring or testing fork it is easy to show that the earth return current flows through the whole mass of the sand, and with a little trouble the general form of the equipotential surfaces can be ascertained.

If the wires representing "pipes" are bent so that they have a loop in them which emerges above ground, this loop can be cut, and a sensitive ammeter or galvanometer inserted, so as to indicate the current flowing through the "pipe." In this manner it can be proved that when a pipe runs approximately parallel to the track, and when it is found to be positive to the rails near the generating station, and negative to the rails at distant points, there is a current flowing in the pipe from the far end towards the station end. If the pipe runs more or less transversely to the line then little or no current will appear in it.

In the case of actual pipes and real street railways it is an impracticable matter to make such tests as shall show whether there is a current flowing in the pipe or not. We can only infer its existence when electrolytic corrosion has made its appearance.

From experiments made with the above model, I am led to believe, if pipes or wires were laid down imitating the form or arrangement of the actual main pipes, and if a track were laid down imitating the plan of the real track, that useful information might be gained as to the localities, if any, in which electrolytic trouble may be expected.

It is, of course, obvious that a model on a limited scale can only very roughly represent the true state of affairs. In any actual case it is an exceedingly difficult, if not impossible, matter to predict the path along which the earth return current will distribute itself. It depends on unknown conditions as to rock and soil conductivity due to moisture, geological formations, subsoil water, infiltrations of sewage, brine springs, the conductive effect of buried pipes, leakage of water, gas and the nature of the car traffic at the moment. There is, however, a drift of current through the earth from the most

* Paper read before the British Association at a joint meeting of Sections A and G, Bristol, Eng., Sept. 12, 1898.

* If the "rails" in the model are made of carbon and the "pipes" are made of iron wire, there will be a constant potential difference between them of about 1 volt, due to the carbon, damp sand and iron forming a voltaic couple. This constant potential difference, however, can be taken into account in measurement, and does not interfere with the detection and measurement of those potential differences set up by the flow of current through the sand, which is originated by the external electromotive force.

distant portion of the line towards that point or points where the negative dynamo terminals are attached to the rails. The question of pipe corrosion is wholly bound up with the degree to which this return current takes advantage of pipe conductivity to help it on its way or is carried by the pipes as well as by the earth. This is not prevented by the fact that the earth resistance, taken as a whole, may be very much less than that of any line of pipe, but it is affected to a considerable degree by the resistance due to pipe junctions, or to the surface resistance afforded by oxidation of the pipes by which the entrance of current into them is hindered. The above statements can be proved by the use of wires imitating pipes badly jointed or partially insulated, and buried in the sand of the model electric railway just described, and a model of the above kind proves itself to be exceedingly useful for lecture or demonstration purposes in addition to its employment as a means of testing theories.

It appears, then, that the following statements may be taken as correctly representing facts in the case of electric street railways having uninsulated rails used as a return circuit:

(i) No amount of bonding of the rails, if uninsulated, will entirely prevent the flow of current through the adjacent earth, when there is any difference of potential between different parts of the line, and even with good modern bonding, or even continuous rails, a fraction, not inconsiderable, of the whole outgoing current may return by the earth.

(ii) Some portion of this current will pass through subterranean pipes, the amount being determined by—

(*a*) The general or local subsoil conductivity.

(*b*) The electric conductivity and continuity of the pipe lengths and depending on joints and material.

(*c*) The length and disposition of pipe, and its position as regards the average equipotential surfaces in the earth, when the line is working.

(*d*) The condition of the pipes as regards oxidation or incrustation with non-conducting oxides or protective covering. The position which seems most likely to be favorable for the passage of current into the pipe is when it extends for some distance parallel with the rails and passes near the point of junction of the return feeder to the power station and the rails, and when it is new or fairly clean and well jointed—all conditioned, of course, by the general earth conductivity.

(iii) The danger areas are those regions in which the pipe current, if it exists, leaves the pipe to get back into the rails or return feeder, or even into the same pipe again, but mere difference of potential between the pipe and the rail is not in itself a source of danger to the pipe. There must be, in addition, electrolytic conduction of current out of the pipe into adjacent soil which contains electrolyzable salts and the necessary moisture.

(iv) If electrolytic conduction out of the pipe exists at any places there is no absolute security in the Board of Trade limit of 1.5 volts for the potential difference of pipe and rail, except in so far that the less the voltage the less rapid will be the damage. Electrolytic corrosion may take place when only a small fraction of a volt difference of potential exists between the iron pipe and the adjacent portions of the rail return.

(v) The conditions most to be feared as provocative of pipe destruction are when certain local soil conditions exist near the places where the pipe is most positive to the rail. The presence of soluble chlorides in the soil, produced by sewage, brine springs, infiltration of sea water, if near the sea, solution of chlorides of sodium, potassium or magnesium or other salts present in the soil produced by water due to pipe leakage or natural accumulation by rainfall saturating the soil, set up at once conditions permitting electrolytic conduction, and the resulting liberated acid or chlorine ions attack the cast-iron pipe. In rapidity of destruction under this action, a new clean pipe may possibly succumb even sooner than an old one protected by a dense adherent coating of oxide, which is not a very good conductor. The time which any such action takes to reach a stage destructive to the pipe will be obviously less the more the electrolytic action is concentrated on a limited area of pipe surface.

In designing an uninsulated rail return traction system, the probability of the above-mentioned conditions occurring should not be ignored. Even if actual perforation of the pipes does not occur, there may be an "ageing" action which shortens the life of the pipe.

(vi) As the conditions determining possible pipe corrosion are numerous and not at all easily predetermined, it is important in the case of every electric traction system with uninsulated earth returns that an electrical survey should be made at intervals, setting down on a plan, showing rails and pipes, the potential difference between them at various places. Within the danger area a close watch can then be kept, whenever the ground is opened up for any purpose, for evidence of destructive electrolytic action on buried pipes.

In the above short summary of the causes and conditions of pipe electrolysis, no reference has been made to the question of remedy when it is found to exist. To deal with this portion of the subject properly would require more time than is at present at my disposal. All that has been here attempted is to show that, even working under Board of Trade regulations, it must not be assumed that the danger does not exist.

ELECTRICITY IN MODERN SURGERY.

Address by Dr. C. R. Dickson, of Toronto.

The following is part of an address delivered by Dr. C. R. Dickson, of Toronto, president of the American Electro-Therapeutic Association, at the recent meeting of that organization in Buffalo, and is of interest as shedding light on a subject which is as yet not thoroughly understood by the general public:

"For many years past the thoughts of those who are interested in the many branches of this wondrous subject, electricity, have turned to Buffalo, and it has been the Mecca of the Electric Pilgrims. On its outskirts the wildest dreams of the Arabian Nights have been outdone. Science, ever triumphing over nature, has harnessed that most beautiful of all nature's handiwork, and as though by the subtle touch of the magician, the very country has been transformed and solitary fields have become veritable hives of human industry, the outcome of the mighty power of Niagara transformed and transmitted. Massive factories are run on every side where but a few short years ago were found naught but vacant lots. To us, witnessing it for the first time, it is a milestone of progress, illustrating man's ingenuity, the triumph of his brain.

"The necessity for the existence of such an association as ours has been questioned, not only here but elsewhere; hence it may be necessary to explain our position. It has been asked 'Why should there be such an association? Electricity is only one of many therapeutic agents, and it would be absurd to have a separate association to consider each therapeutic agent.' At first glance this may seem a quite rational question. Our colleges teach us how to administer opium and its various derivatives, therefore the necessity for an opium society does not exist; but do our colleges teach us anything about electricity worthy of the subject? The answer to this question is quite unnecessary in the presence of the members of our association. Anyone should be depended upon to prescribe and administer the ordinary, or even extraordinary, remedies to carry out any regulation form of treatment. But I, for one, should fear to trust myself to the tender mercies o the general practitioner of to-day, did he in his wisdom consider it necessary to use this agent, electricity, unless he had paid some special attention to the mastery of it. The contention is an absurdity unworthy of America, the vaunted land of progress, and of Buffalo, the electrical city. In my own benighted land, even we are more enlightened than that. This is an age of specialism.

THE AGE OF SPECIALISM.

"The old-time practitioner, then the physician and surgeon, seems passing away. Surgery is being divided and subdivided, until at one time we feared that we were to be confronted with an appendix surgeon. Our patients are reaping the benefit of all this. Why, then, should we call a halt? No! Let onward be our cry. The time is past when a physician, the proud possessor of a magneto-electrical machine turned by a crank, considered his armamentarium electricum quite complete. One has but to glance at our programme to see to what extent electricity may be used, and used to advantage. A programme such as ours should prove a perfect revelation to him who has not kept well up to this progressive age. Could such a programme or one-hundredth part of it be intelligently discussed in any other existing society to-day not dealing distinctly with the subject? No! I greatly fear it would be a hidden book, a stumbling block.

"The hope of the future now lies in those who are thronging wisdom's halls, and it is a subject for congratulation that this association is to be asked to take action, bringing the needs of the hour before the authorities competent to deal with them. The student with mind as yet unwarped by prejudice must be in a position to obtain a comprehensive, intelligent grasp of the whole subject, that he may turn his theories to practical account in his professional career. But even he, unless endowed by those inestimable blessings, common sense, patience and gentleness, will find his efforts unavailing, and he must be a close observer of nature and her laws, seeking to assist rather than to combat her. Electricity is an agent most powerful for weal or woe. A great responsibility rests upon our educators, and the sooner they awake from their strange lethargy the better will it be for our reputation as an enlightened, progressive, scientific profession. The commercial world has taken such advantage of the rapid strides of electricity as a science with fixed laws that we have laid ourselves open to the charge of neglect. Let us hasten to make amends for the past, and remove some of the reproaches that rest on this, the noblest profession in this fair world.

OBJECT OF THE ASSOCIATION.

"Our association was organized some eight years ago because it was felt that the subject of electro-therapeutics could not be discussed in any existing society in a scientific and practical manner without controversial digressions of no value whatever. It was felt and felt strongly, that electricity had been left too long to the charlatan, the incompetent and the unscrupulous. It was also felt that we had another foe of hardly less dangerous character, the overzealous.

"To combat all these and cultivate and promote knowledge of electricity wherever it can be of service in medicine and surgery is the object of our association. It must be admitted that we are setting about this in the most practical manner possible. In fact, I know of no other association in which more practical or more useful work is being done. To carry out this idea successfully we have associated with us other than purely medical practitioners, and the association has proved a most happy one and fruitful of nothing but good. Thus the electrical engineer and expert study electricity's laws and note its action upon inert matter. The biologist and physicist go a step farther and study these laws in their action upon living tissue, and their labors are turned to practical account by the physician and surgeon.

"The clouds are breaking on our horizon. On my side of that imaginary boundary line we find increasing interest being manifest, and it gives me the greatest satisfaction to say that my own warmest friends in the city of my adoption are the men who stand in the front ranks of medicine and surgery, and electro-therapy has a recognized standing, inasmuch as special departments devoted to it are to be found in our public hospitals. I have had the honor to organize and now to preside over four such departments in as many hospitals, and more intelligent inquiries are being made by the students of the various medical colleges, all of whom have access to my clinics."

ELECTRIC LIGHT AND POWER AT THE HOFORS IRONWORKS, SWEDEN.*

Amongst the various works visited by the Iron and Steel Institute in Sweden last month, those of the Hofors Ironworks were, perhaps, the most interesting. These works are the oldest in the province of Gestrikland, and were founded in the beginning of the seventeenth century. Hofors and many other small ironworks in the neighborhood got their ores from the Torsaker Mines, which were quite sufficient to meet the small requirements in old times. However, as the output from blast furnaces and forges grew, also ores from Norberg, and later on from Bispberg and Wester Bergslagen, began to be used. The works have grown most rapidly, as all new improvements in iron manufacture have been adopted. The power for the works at Hofors was at first obtained from a 92 ft. fall near by, but with extensions the water available proved insufficient. More power was therefore secured by an electrical transmission scheme from a waterfall of 100 ft. at a distance of about 1½ miles from Hofors. There six turbines furnish a total of 1,400 HP., which is used for the rolling-mills, auxiliary machinery and machine shops. These were, we believe, the first rolling-mills driven exclusively by electricity. The present yearly output of the works is about 11,000 tons of pig iron, 18,000 tons of Bessemer and open-hearth ingots, and 15,000 tons of rolled, hammered or pressed material, as finished product. Besides those who work in the woods and the mines the company employs in the works about 500 men.

Description of the Electric Plant.—Electricity is used at Hofors for both lighting and transmission of power. The lighting plant is very simple in character. It consists of a continuous-current three-wire system, which is fed by two generators of 30 HP. capacity each. The generators are both belted to the shaft of a 100 HP. turbine. The voltage is 110 volts on each side. Arc lamps as well as incandescent lamps are used. In the daytime a number of small motors (some 40 HP. together) are also fed from these circuits. While the electric light plant just mentioned has nothing peculiarly interesting about it, the transmission of power system, on the contrary, is of a character which justly has attracted the great interest of electricians as well as of technical people in general. Not only is it a fact that this plant was the first one built for furnishing power for rolling-mills exclusively by electricity, but also these motors were, at the time when the installation was erected, the largest of their type in any part of the world. The generating plant at the primary station is situated at the 100 ft. waterfall which has previously been referred to. There are six turbines in all. Two of the turbines are of quite a special design, each being composed of two wheels, thus making it possible to obtain on the same shaft either 300 HP. at 480 revolutions per minute, or 200 HP. at 320 revolutions per minute. The four remaining turbines have only one wheel each, and are of the following sizes: two giving 300 HP. at 480 revolutions per minute, one for 150 HP. at 515 revolutions per minute, and, finally, one for 40 HP. at 720 revolutions per minute. The well-known three-phase system is used.

The generators are directly connected each to its own turbine. Each of the 300-HP. turbines runs a 300-HP. four-pole three-phase dynamo, working at a voltage of 900 volts (measured from the neutral point to each of the terminals). The field magnets, which are made of cast iron, are stationary, while the armature with laminated core revolves. The armatures have a diameter of 37½ in. and a laminated length of 28½ in. The normal frequency is unusually low, being only 16 complete cycles per second. The energy required for the excitation of the field of each generator is 2,700 watts. The weight of one of these generators is about 19 tons. The 150-HP. turbine is also coupled to a three-phase generator of corresponding capacity, giving 900 volts at a frequency of 60 cycles per second. This generator has 14 poles; otherwise it resembles the larger machines in design, as well as to materials used for its construction. The diameter of the armature is 33½ in. and the length of lamination 21 in. The excitation at full load is 1,500 watts. Two continuous machines, both coupled to the shaft of the 40-HP. turbine, are provided to excite the alternators. These machines also provide the current for lighting the power-house and some private houses. One switchboard made of white marble serves for the whole. Each three-phase generator is equipped with three fuses, one three-pole switch, ammeter, and field rheostat. Three of the large generators are connected each to its own system of overhead conductors supported on wooden poles from the power-house to the works, whereas the fourth serves as a stand-by in case anything should happen to any one of the others. The 150-HP. generator also operates on a line of its own. Each of the exciters can furnish current for the excitation of all the three-phase machines simultaneously.

The line consists of nine copper wires of 9 mm. diameter each and three wires of 5.5 mm., all mounted on the same poles. The length of the line is about 1½ miles. Four motors, each of 200 HP. capacity, are installed for driving the rolling mills—one for the medium train, two for the wire mill, and one for the "fine" train. Each motor is fed from its own generator independently of the others, so that more than three motors cannot run at the same time if loaded to their full capacity. These motors are inductive three phase motors with short-circuited armatures. They have four poles, and run about 460 revolutions per minute. The diameter of the rotors is 35 in., and the length of the lamination 29 in. The starting of the motors is entirely done in the power station. The generator and its motor are, when standing, left connected to the corresponding line. Then the excitation is put on the generator fields, and the gates of the turbine are opened. In this way the generator and motor start about the same time. When started in this way the motors develop their full-load torque when starting without the use of any resistance boxes. Telephones are used between the works and the power station. In addition to these large motors which drive the mills there are also 13 smaller motors of an aggregate capacity of 210 HP. These motors get their current from the 150 HP. generator, the larger motor being fed directly from the line voltage, and the smaller ones by means of transformers. Some of the motors are fitted with short-circuited rotors and others are arranged with complete secondary windings for securing good starting torques. This plant has now been running for about two years, and has given perfect satisfaction.

Messrs. Karl Wallin and Andersson and Ernst Danielson made a report as experts on this plant in July last on behalf of the company to see if the plant fulfilled the conditions in section 2 of the contract. They report briefly as follows: "The power of one of the turbines of the power plant was measured by means of a brake. When carrying out this measurement the armature belonging to the corresponding generator was removed, all the gates of the turbine were fully open, and all the other turbines in the power-house were shut down. A series of observations were made in order to find the power of the turbine at different speeds. Afterwards the brake was removed from the turbine shaft and applied on one of the motors in the works, and at the same time the armature of the generator was put in place and connected to the turbine shaft. On account of these observations it was accordingly only necessary to take readings of the number of the revolutions of the turbine in order to determine the corresponding horse-power. The motor in the works was then run on the brake, and its corresponding power was obtained. As a result of these measurements, and after allowing for the energy which was absorbed in the field magnets of the generator, its rheostat and exciter, we have obtained at normal speed (480 revolutions per minute of the generator, corresponding to a speed of about 456 revolutions per minute of the motor) an efficiency of 75 per cent., and at 520 revolutions per minute of the generator, corresponding to 494 revolutions per minute of the motor, an efficiency of 72 per cent. The corresponding horse-power of the motor was 244 HP. at 456 revolutions per minute, and 216 HP. at 494 revolutions per minute. In conclusion, the experts say that the entire plant is very well laid out, and that, as far as they have been able to ascertain, everything belonging to it is manufactured of the best materials and with the greatest care. They especially praise the ample and solid construction which is a characteristic feature of the whole of the machinery.

* From the *Electrical Engineer*, London.

The Use of Wireless Telegraphy to Avert Collisions at Sea.

M. Edouard Branly, best known in England as the inventor of the so-called coherer, now so generally used in connection with the transmission of electric signals without connecting wires, has contributed an interesting note on the above subject to the Academy of Sciences. In foggy weather it is obvious that there would be a great gain if ships could make their presence known to each other when still some few miles apart. The use of foghorns is not always efficient for this purpose; M. Branly proposes to use electric signals. It is necessary that each ship should be furnished with both transmitters and receivers, and further, that the transmitters on one ship should be able to affect the receivers on others without disturbing its own receiving apparatus. With powerful radiators and sensitive receivers M. Branly states that metallic screens are ineffectual unless the receivers are entirely enclosed. It is, therefore, proposed that an arrangement should be adopted by which a receiver is protected from the influence of the transmitter on board the same ship during the time that the latter is acting, being subsequently exposed to the action of transmitters on other ships. It is stated that it is not necessary to enclose the whole of the receiving circuit, the most sensitive portions alone requiring screening. It is further of importance that the bearing of a neighboring ship, together with its speed and the direction of its motion, should be known. In the first place, a receiver, screened so as to be open to external influences only on one side, might serve to determine the bearing of the ship from which the electric waves are emitted. Further, M. Branly has found that a single spark in a transmitter is capable of affecting a receiver only when the distance between the two is small; to produce effects at greater distances, the number of sparks must be increased. M. Branly has invented certain forms of metallic envelopes for the receiving apparatus which permit of the distance of the transmitter being estimated from the intensity of the action of the receiver.—*Electrical Engineer, London.*

LONDON NOTES.

[From our London Correspondent.]

Municipal Telephone Systems.

It seems that the municipal working of telephone systems in this country is to be an accomplished fact. The Parliamentary Committee recommended competition as a remedy for the evil effects of the existing monopoly and favored municipalization. A license is now granted by the Postmaster General to the Corporation of Glasgow, which has been agitating for it for several years past, but has until now been refused. If the Glasgow Corporation is successful in securing the necessary powers from Parliament, it will equip a telephone system, presumably to compete with the National Telephone Company. This municipal license is only granted until December 31, 1911, when the National Telephone Company's rights also lapse. It is stated that municipal licenses are to be granted to other towns which are applying.

Sunderland Electric Trams.

The Sunderland Corporation recently sent a deputation to the Continent to inquire into electric traction, and the borough engineer reported upon cable traction, the electrical engineer (Mr. J. F. C. Snell) going very exhaustively into the comparative merits, costs, etc., of the trolley, conduit, accumulator and other electrical systems. The report of the deputation brings together a mass of very important descriptive detail and general data, and it has convinced the municipal authority of the benefits of electric traction, for the Corporation has just pledged itself to the equipment of 23 miles of single track. Tenders have not yet been invited for the electrical contracts but they will be very shortly, therefore the following estimate of plant required will possess interest for American manufacturers: The 23 miles of single track has to be laid with 96 lb. girder rails on a concrete bed, and the cost of this, including fishplates, tie rods, etc., is put at £109,150. The bonding of rails will cost £6,900. The line equipment, poles and rosettes, insulators, trolley wire and all apparatus fixed complete is put down at £17,250. Feeder cables will be laid complete in "ducts," with section boxes, manholes, etc., at a cost of £9,200. There will be required 60 single deck motor cars, trolleys, controllers, with two motors and brakes, etc., cost £42,000. Thirty single deck trailers are estimated at £6,600. and the construction of two car sheds will cost £20,000. Five per cent. is put down for contingencies, and as current will be taken from the lighting station a sum is set apart for the provision of the additional traction plant which will be necessary. This will bring the expenditure up to about $1,250,000.

California Power Plants.

The development of electric power for industrial uses is almost phenomenal in California, and this fact is notably illustrated in the case of the two big plants in the vicinity of Redlands. It is stated that it requires 34,560 pounds of coal to operate one-horse power for one year by means of steam. The Redlands plant produces 1,000 horse power in electricity, in addition to the one producing 2,000 horse power. Further, the plant of the Southern California Power Company, producing 4,000 horse power, makes 7,000 horse power in electricity by the two companies in Mill Creek and Santa Ana canons—equivalent, that is, to the consumption of nearly 121,000 tons of coal per year in the making of power by steam. With coal therefore at $4 per ton this means $483,840; dividing this by 300, as the number of working days, gives an average of 403, the equivalent of this number of tons of coal mined per day, and, as the water flow is continuous, these plants are, as it were, inexhaustible mines producing this enormous output.

A Kansas City Editor Lauds the Trolley.

The following is clipped from an editorial in the Kansas City, Mo., *Star*:

"Fifty years hence Kansas City, instead of being a compact mass of masonry, will be built in long strips along the lines of rapid transit. The massing together of buildings in great cities is a result of the lack of quick transportation. Kansas City began to spread out with the advent of the cable car. Its topography was such that the first serious problem was how the town could attain a magnitude beyond the radius of a mule's power to pull a car along a rail. Kansas City owes its impetus toward greatness to the solution of this problem by the cable car. The trolley is a vastly greater appliance. Not only will the trolley refashion Kansas City, but it will have an influence on all the cities of the world. The influence of the trolley on Kansas City will be marked a decade hence and notably in a quarter of a century.

"The signs of the times point to electric transit as the agent for the regeneration of cities, the destroyer of slums and the benefactor of the humble. Progress does not stop for individuals. Lots which are occupied by buildings to-day some years from now will be growing garden truck, and pastures that graze cattle to day will be the valuable corner lots of another generation.

"Kansas City is soon to exchange its cable cars for trolleys. Thus is progress superior to sentiment. There is much to attach Kansas City to its cable lines, for they marked its bound from a border town to a metropolis. The institution of the cable cars signalized the beginning of the boom. And what a boom it was! It was a time when mediocrity rolled in wealth and genius owned the earth. Except for seeing and riding upon those cable cars the people could not have believed the evidence of their senses. The cable was a giant in those days. It harnessed itself to the city and stretched it out miles beyond the wildest dreams of the border days. When the crash came the cables, still traversing the streets from which the throngs had fled, encouraged the people.

"Kansas City continued to hold up its head and claim to possess the finest cable car system in the world. When prosperity returned, the cable car gongs seemed to clang out a note of triumph. Suddenly the trolley car sprang into existence and the cities which still traveled on horse cars while Kansas City rode on cable cars forged ahead with miles of swift electric transit. Kansas City is a devotee of progress and improvement, and much as it cherishes the cable cars it hails the new motive power. The king is dead; long live the king!"

The Eugene Field Monument Fund.

We cheerfully give space to the following note from Mr. A. L. Swift, secretary to the committee having charge of the above fund, and invite attention to the advertisement bearing on the matter which will be found elsewhere in this issue. The object in view appeals strongly to every one who has read Mr. Field's productions in prose or verse:

Editor ELECTRICITY.

DEAR SIR: At a meeting of our committee held Friday, September 23, it was directed that you be notified of the passage of a vote of thanks to the newspaper and periodical press for their generous assistance in this worthy movement. The affairs of the fund are in excellent shape and but a few thousand dollars remain to be raised, when we shall be able to erect a very creditable monument and set aside a liberal fund for the family of the lamented 'Gene Field. The committee has been unable to make any progress at all during the past six months, because of the war, the warm summer months, etc. Owing to the fall sale of books and the holiday subscription to the fund through "Field Flowers," we hope to finish our labors by February 1st. This can only be done by your continued co-operation and help in this final effort for success, which is only made possible by the assistance of a generous press. As you are aware, all the advertising has been donated, and without exception almost by every paper and magazine of note in the country.

Let this last appeal enable us to all join in one final effort for the success of this movement. Without it we will fail.

Please accept the sincerest thanks of our committee and of Mrs. Field. Very sincerely yours,

Chicago, Sept. 28. A. L. SWIFT, Secretary.

LEGAL NOTES.

The suit of Thomas F. Morrin, of Jersey City, against the Edison Electric Illuminating Company of Brooklyn and the Clonbrook Steam Boiler Company, to recover damages for infringement of patent, was decided in favor of the plaintiff in the United States Circuit Court at Brooklyn on the 5th inst. The amount of damages will be settled by a referee.

An injunction restraining Receiver J. L Williams from using any of the assets of the Franklin Electric Light Company of Cape May, N. J., or demanding its books, has been issued by the Court of Chancery. The receiver is permitted to exercise his functions only in carrying out the lighting contract with the city.

The report of Referee Frederick Chormann for the sale of the property of the Buffalo, Kenmore & Tonawanda Electric Railroad, to satisfy the demands of the Fidelity Trust & Guaranty Company, was ratified and confirmed by Justice Childs on the 4th inst.

The Bullock Electric Manufacturing Company of Cincinnati, Ohio, by Attorney C. V. Edwards of New York, has filed a bill in the United States Circuit Court at Baltimore against the Evening News Publishing Company, alleging an infringement of the complainant's patent of an improvement in starting electric motors, and asking an injunction and accounting.

John Jenkins, a real estate dealer in Brooklyn, N. Y., was given a verdict for $400 in the Supreme Court, Brooklyn, on the 4th inst., as damages for having been ejected from a Fulton street car of the Brooklyn Heights Railroad Company. Jenkins in December, 1895, secured a transfer from the Montague street car line of the same company, but allowed several cars to pass, as he could not obtain a seat in them. When he did board a car the conductor refused to accept his transfer, and upon his refusal to pay an additional fare forcibly ejected him. The case at its first trial was dismissed, but the Appellate Court ordered a new trial, Justice Woodward, who wrote the opinion, saying that the plaintiff had a perfect right to wait until he could obtain a seat, without regard to the company's time limit. The second trial resulted in the above verdict. The plaintiff sued for $5,000.

Judge Colt of the U. S. Circuit Court has appointed William P. Clarke of Peabody, Mass., receiver of the Newburyport & Amesbury Street Railway Company on the application of the Mechanics' Savings Bank of Providence, R. I. The railway company failed to pay the September interest on its bonds.

The American Electrical & Maintenance Company of 451 Greenwich street, New York, went into the hands of receivers on the 4th inst., Justice Smyth of the Supreme Court having appointed Aldred K. Warren and Francis Higgins receivers in proceedings brought by the directors for the voluntary dissolution of the corporation on the ground of insolvency. The liabilities are $35,199, nominal assets $29,120, actual assets $17,398, consisting of book accounts, tools, patterns, and materials in process of manufacture. The order to show cause for the dissolution was set down for January 16 before Hamilton Odell, referee. The bond of the receivers was fixed at $30,000. Aldred K. Warren is president of the company, James R. Steers vice-president and Nicholas H. Savey treasurer. The trouble of the company is ascribed to the exhaustion of its cash capital. Several of the large stockholders put up the money to run the concern, and the other stockholders declined to contribute for the continuation of the business. The principal creditors are the Tradesmen's Bank, $6,000; A. H. James, $3,120; A. K. Warren, $2,834; Leon Abbett, $1,840. There are about 180 creditors. The company was organized principally for electrical machinery repair and inspection. The business was started in 1892, and the present company was incorporated in July, 1897, with a capital stock of $250,000.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING.

Bridgeport, Conn.—The debris and machinery in the burned electric light plant at Pleasure Beach are being removed by a corps of laborers. In the spring it is intended to erect another power house, which will occupy an isolated position, and an entertainment feature will be placed where the electric light station was burned down.

Chicago.—A new electric light plant, to cost $200,000, will shortly be added to the Illinois Steel Company's property at South Chicago.

Columbia, Ind.—The council has ordered the purchase of the entire electric lighting plant here owned by private parties. The price is $21,600 and it is to be paid in ten annual payments.

Corbin, Ky.—J. J. Hagan, a leading druggist of this city, has leased the plant of the Corbin Electric Light & Power Company, and is overhauling and improving it in every department.

Crescent City, Fla.—The Pierpont Manufacturing Company has been granted an electric light franchise in this town for twenty years, the town having the privilege of purchasing the plant at the expiration of ten years.

Elizabeth, N. J.—It is reported that a number of our merchants are about to organize a company to set up an independent electric lighting plant, being dissatisfied with the present cost of lights.

Fitchburg, Mass.—The heavy smoke which accumulates in the Hoosac tunnel has destroyed the advantages of the electric light system and the Fitchburg Railroad Company has caused the lights to be removed. However, arrangements for a better system are being considered and unless these fail persons using this route may soon see an electric engine drawings trains through the tunnel.

Florence, Ala. The Florence Milling Company contemplates establishing an electric light plant.

Herkimer, N. Y.—A special election is to be held on October 14 to ascertain the will of the citizens in regard to bonding the town in $13,000 to put in an electric light system.

Litchfield, Ill.—Proposals will be received by the city clerk until the 22d inst. for furnishing electric lights for this city and also for an electric light plant.

Manawa, Wis.—An electric light plant for this place is definitely decided upon; the Little Wolf River Lumber Company will furnish the power.

Newark, N. J.—The People's Light & Power Company has made a new rate for house lighting in the form of a reduction of one tenth of a cent. per hour per lamp, and will make the list prices of commercial and incandescent lighting the same. Heretofore house lighting was listed at a rate equivalent to three-quarters of a cent per sixteen candle power lamp per hour, and commercial lighting was charged for at the rate of sixty-five-one hundredths of a cent. The new rule leaves both classes of lighting at the latter figure, so far as the list prices show.

New York.—The United Electric Light & Power Company has issued the following notice to its customers with reference to the supply of electricity: "All bills for current supplied on and after October 1 will be rendered at the new rates, a schedule of which will be sent you prior to the rendering of October accounts. Your special attention is called to our power service, which owing to the use of Tesla induction motors without commutators and other complicated devices, is vastly superior to any other power service offered. We are giving the matter of the introduction of power apparatus special attention, and are prepared to make our rates for power service especially attractive." The United Electric Light & Power Company owns through the Westinghouse Company the exclusive rights under the Tesla patents within the Borough of Manhattan.

Philadelphia.—The bids for city electric lighting for the year 1899 were opened by Director Riter on the 4th inst. The bidders were the same as last year, but the prices were considerably less. It is estimated that the reduction will be about $30,000. The bids ranged from 29 cents to 39 cents for each light per night according to locality and other conditions. All the companies bidding have their own territory and there is consequently no real competition.

Pratt City, Ala.—P. G. Shook and associates have been granted a franchise here to erect an electric light plant to cost about $10,000.

Whitesboro, N. Y.—A special election is to be held here on the 24th inst. for the purpose of voting on propositions that involve a preference for electric or Welsbach lighting for the village.

Wilkes-Barre, Pa.—The parties who recently purchased and consolidated the gas interests of Wilkes-Barre—Edward C. Jones, a banker of New York, and President Abram Nesbit and Cashier E. W. Mulligan of the Second National Bank of Wilkes-Barre—are said to have also purchased the Wilkes-Barre Electric Light Company.

Uniontown, Pa.—The lighting company of this city has made itself obnoxious to the business men and they propose to establish an electric light plant of their own.

Worcester, N. Y.—The town board have made a contract with John Van Benthuysen to light the village with electric lights, the plant to be in operation by January 1.

STREET RAILWAYS.

Albany, N. Y.—The map and profile of the route of the Albany, Helderberg & Schoharie Electric Railway Company have been filed. Notices will be served at once on property owners through whose property the proposed road will go. If the road is built according to the route filed it will go through the villages of Normansville, Elsmere, Delmar, Slingerlands, New Scotland, New Salem, Clarksville, Helderberg, Indian Ladder, Thompson's Lake, East Berne, Berne, West Berne, Galupville and Schoharie.

Bar Harbor, Me.—The project of building an electric railway from Winter Harbor through Goldsboro and connecting with the Washington County railroad is now under consideration by John G. Moore, J. Montgomery Sears and other well-known capitalists.

Bellows Falls, Vt.—Books have been opened for subscriptions to the stock of the proposed road from this town to Saxton's River. If $20,000 is subscribed the directors will probably increase this amount to $50,000. It is hoped to have cars running by December. The officers of the road are: J. H. Holton, president; A. M. Swain, vice-president; J. J. Flynn, treasurer; Geo. A. Weston, of Bellows Falls, secretary, and Geo. R. Wales, assistant secretary. The directors are: E. C. Kennedy, J. J. Flynn, A. O. Humphrey and J. Holton, all of Burlington; A. M. Swain and Geo. R. Wales of Bellows Falls, and J. F. Alexander of Saxton's River.

Clarksville, Tenn.—Col. J. F. Shelton, in company with a surveyor, has gone over the routes between this city and New Providence and laid out the lines of a proposed suburban electric car line. The length of the proposed line will be about three miles, and if built will connect the largest suburb of Clarksville with the city.

Cripple Creek, Col.—The Colorado Springs & Cripple Creek electric road will probably be built very soon, as some wealthy New York and Baltimore people have become interested in the scheme. The road will start from Colorado Springs and run to Manitou, where it will connect with the Pike's Peak cog road. It will run over the cog road to Windy Point and from that place down into Cripple Creek. Electricity will be used as a motive power on the entire system, as it will supplant the present power on the cog road. Power will be generated at the falls at Lake Moraine where it is believed there will be no trouble in generating 4,200 horse power. It is thought that the line will prove one of the most popular tourist attractions in the world, as few persons who visit Colorado Springs would fail to take a trip over so wonderful a railroad.

El Paso, Tex.—The mule car line here is too antiquated for our people and there is a growing agitation in favor of getting electric cars.

Elizabeth, N. J.—John Kean has secured the right of way for his county trolley road from the township committee of Union. This will enable Mr. Kean to proceed with the construction of his trolley road from Elizabeth to the boundary line of Cranford. This he expects to have completed in about eight weeks.

Fall River, Mass.—An arrangement has been entered into between the Bristol Land & Investment Company and the representatives of a New York electric company relative to the proposed electric road from Providence, R. I., through Warren and Bristol to Mt. Hope, and on this side of the river from Tiverton to Seaconnet Point. The terms of the agreement as understood are that the Investment Company will build the tracks and the New York syndicate will operate the line, furnishing all the cars and promising excellent transportation and frequent trips of the cars. The New York people will also furnish several ferry-boats, bringing them from that city, so that the electric cars can be transported from the dock at Mt. Hope to the Tiverton side.

Greenbush, N. Y.—It is stated that most of the stock in the Greenbush & Nassau Electric Railroad owned by farmers along the route has been purchased at $25 a share by parties who propose to resume the construction of the road.

Hackensack, N. J.—The trolley railway from Leonia to this city which the Bergen County Traction Company is building will be completed in about four months. It will connect with the line running from Fort Lee to Englewood. Ford, Bacon & Davis of New York are the engineers.

Halifax, N. S.—An electric railway scheme of large proportions is under advisement here which if realized will give Nova Scotia the longest line of trolley road in the provinces. It is proposed to build a line from Waverly to Dartmouth and thence to Cow Bay, Lawrencetown, Musquodoboit Harbor and Middle Musquodoboit. The promoters are men of means, with plenty of push, so that there is every possibility that it will materialize if the prospects for the road paying are considered good.

Lansing, Mich.—New York capitalists, accompanied by an engineer, have been inspecting the route of the projected Lansing, Dexter & Ann Arbor Railway with a view to determining if a road built there would be of value to the Detroit & Ann Arbor Railway, in which they are already largely interested. They are said to have been favorably impressed by the examination.

Los Angeles, Cal.—The Huntington syndicate which recently purchased the Los Angeles Railway system are also likely to acquire the Santa Monica line.

Lynchburg, Va.—The street committee of the city council and the Lynchburg Electric Railway & Light Company have agreed on the terms of a contract embodying an extension of franchise and the rehabilitation of the company's road.

Nevada, Mo.—At a special election held in this city recently a proposition submitted by J. B. Quigley to build an electric railway, etc., here was carried almost unanimously. The enterprise Mr. Quigley has in view consists of the railway referred to, also the electric and gas lighting franchise for Nevada, and in addition an electric railway from Nevada to El Dorado Springs, a distance of twenty-three miles, which road will carry both passengers and freight, also the electric lighting franchise for El Dorado Springs. Quigley & Co. have a large part of their material already on hand, and will begin the work of construction at once. It will take an expenditure of $400,000 to build the system.

Newburyport, Mass.—Articles of association of a new street railway corporation, to be known as the Citizens' Electric Street Railway Company, have been published here. The capital stock of the company is $150,000, and it proposes to build and operate an electric street railway in Newburyport, connecting with the town of Amesbury. The directors of the new company are: Charles Goss, of Amesbury; Albert D. Bosson, Chelsea; James F. Shaw, H. I. Bartless, F. L. Atkinson, A. C. Titcomb, Newburyport; W. B. Ferguson, Malden, Mass.

Pine Bluff, Ark.—Col. S. W. Fordyce is interesting himself in the establishment of an electric street railway in Pine Bluff, and will subscribe for $5,000 of the bonds. It is believed that the men holding the franchise will secure aid enough to build the road.

Pittsfield, Mass.—A scheme involving the consolidation of all the electric plants of Southern Berkshire is reported to be approaching consummation. Besides gaining control of these plants a purpose of the promoters is to build an electric railway connecting Pittsfield with Great Barrington. Some of the men whose names are mentioned in connection with the scheme are Daniel Odell and Charles N. Nelson of New York, E. A. Merrill of Minneapolis, and Thomas Greenwood of Great Barrington.

Richmond, Va.—At a public meeting of the citizens of King William a resolution was adopted recommending the issuance of $40,000 of county bonds for the purpose of projecting an electric railway from Richmond through Henrico, Hanover and King William.

Trenton, Mo.—There is a strong movement here in favor of an electric railway connecting this city with Chillicothe, Mo., and meetings are being held to devise means for raising the necessary funds.

Washington, D. C.—The "Star" states that $2,000,000 are to be spent on street railroad construction in the District during the fall and winter, and this by two companies only, the new City & Suburban and the Columbia.

Wheeling, W. Va.—On the 1st inst. a deal was consummated by which the Bellaire, Bridgeport and Martin's Ferry Street Railway Company was absorbed by the Wheeling Railway Company.

Windsor Locks, Conn.—The Springfield & Hartford Construction Company was organized at Warehouse Point on the 28th ult., with a capital stock of $25,000. The company has purchased the charter of the East Windsor trolley railroad which includes about 3½ miles of trolley road between Mt. Tom, Mass., and Wallingford, Conn. The company controls the Springfield & Southwestern Street Railroad and the Suffield & East Granby road.

MANUFACTURING, ETC.

Cleveland, O.—The "Press" says: "The consolidation of the Westinghouse Electrical Company of Pittsburg and the Walker Company of this city will advance the price of electrical goods. S. H. Short, vice-president of the Walker Company, said, Monday: 'Competition between manufacturers has been severe of late, and as a matter of justice to ourselves we will be compelled to advance prices. The Westinghouse Company was formerly our strongest antagonist. I think the combined companies will now be able to control the market.'"

Columbia, Pa.—The Martic Electric Power Company, which has purchased the Susquehanna & Tidewater Canal, running from Wrightsville, York County, to Havre de Grace, Md., is contemplating the introduction of trolley canal boats on the canal, the power to be supplied from its plant in the Susquehanna River, near Wrightsville.

Lancaster, Pa.—H. L. Price of New York has submitted to the Board of Trade a proposition to locate a factory in this city for the manufacture of electrical supplies.

St. Louis.—The capital stock of the Phoenix Carbon Company is soon to be increased from $160,000 to $500,000, for the purpose, it is reported, of meeting the increase of business which is expected to follow settlement of a suit against the National Electric Company of Cleveland, O., in the Federal Court, involving patents that protect the manufacture of goods in which this concern is interested.

Toronto, Can.—The city wants tenders by Wednesday,

November 9, for the supply of a complete electric lighting plant, or for the various portions of the work, viz., engine equipment, counter shaft and pulleys, belting, boilers, feed pump and condensers, water and steam piping, economizers, dynamos and station electrical apparatus, arc lamps, mast arms and lamp attachments, poles and overhead circuits, conduits and cables.

TRANSMISSION PLANTS.

Stockton, Cal.—The Standard Electric Company of California, the company organized by Prince Poniatowski and his associates for the purpose of conducting electricity from the electrical works of the Blue Lakes Water Company in Calaveras County to San Francisco, and for supplying intermediate towns, will immediately apply for a franchise covering the city of Stockton, allowing the company to distribute its power throughout this city. The idea is to furnish electricity for both lights and power. About 1,000 horse-power will be available here at the start. The intention is to continue the line on to San Francisco. Rights of way have been secured from the power works to that city.

Venezuela, S. A.—According to recent advices a French company has secured a concession from the Venezuelan Government to construct an electric railway line 43½ miles in length. The road is to connect Cumana and Cumanacao, and the electrical power is to be generated by the waterfalls of the mountain streams. The company has sent engineers to Cumana to begin the survey.

MINES, ETC.

Aspen, Col.—The electric current supplied from a small power house at the Mollie Gibson mine is used in the operation of an underground railway connecting that mine with the Argentum Juniata mine and furnishes surface and underground lighting for both properties. The saving through the use of electricity at the mines is about $1,000 a month.

COMPANY MATTERS.

Hartford, Conn.—The East Windsor Electric Railway Company has filed a certificate of the acceptance of its charter granted by the General Assembly at the session of 1897.

NOTES FROM A CORRESPONDENT.

Schenectady, N. Y.—Mr. Osmer Slade, a foreman in the armature department of the General Electric Works, was married on Tuesday last to Miss Carr, of this place.

Albion, N. Y.—The Albion Power Company has purchased the local electric light plant. This plant has been in operation for several years. The Power Company now proposes to extend the plant and to operate it by water power secured at Waterport, six miles away. A contract has been let for constructing a dam at Waterport and for putting in the wiring and machinery necessary for the extension of the plant.

PERSONAL AND MISCELLANEA.

Hill Williams, formerly superintendent of the Upper Appomattox Electric Company, Petersburg, Va., died at Milford, Mass., two weeks ago. He had been a sufferer from a brain disorder for a long time.

J. B. Stevens, electrical engineer of the L. I. Fletcher Company of Boston, has assumed charge of the Cumberland Illuminating Company's plant at Great Falls, Maine. Mr. Stevens was formerly in the employ of the General Electric Company as constructing engineer.

Col. Eugene Griffin of the First Regiment U. S. Vol. Engineers is recovering slowly from the fever which caused his return from Porto Rico. He is still confined to his home at Ardsley, Westchester County, N. Y. When fully restored to health, he will rejoin his regiment, which is now engaged in military engineering and construction work in Porto Rico.

On Friday last at Waterville, Conn., R. G. Cleveland, a druggist, was cleaning a desk with the assistance of a clerk, John Turgeon. Each held the bulb of an incandescent electric lamp. Each received a shock which threw him writhing to the floor. Neither could relinquish his hold. Dr. Holroyd, who was in the store, seized Turgeon, and was himself thrown down and badly burned. Finally both men were wrenched from the lamps, but it was several hours before they recovered. Their hands are badly burned, and part of their clothing. The accident was due to the burning out of a controller on a pole near by. There were 1,100 volts in the current. A damp floor assisted in forming the dangerous circuit.

G. M. Esterly, superintendent of the Dawson City Electric Light & Power Company, was in Seattle, Wash., recently, and took passage for the Alaskan city on the steamer Dirigo in which he also shipped about 35 tons of electrical machinery. He stated to a Seattle reporter that arc lights at Dawson City bring $14 a night and incandescents from 50 cents to $1.25, and even at these seemingly enormous prices the supply is far below the demand. The Dawson City Electric Light & Power Company has the following officers: President, William Chappell, formerly of Wisconsin; vice-president, Alexander McDonald, a well-known Klondiker; secretary, Attorney Falcon Joslyn, formerly of Seattle; treasurer, D. Doig, manager of the Bank of British North America at Dawson; manager, J. D. Trenholme of North Dakota; superintendent, G. M. Esterly, for five years general superintendent of the Esterly Twine Binding Harvester Company of Whitewater, Wis. Captain Donald Alson, formerly of Seattle, is electrician of the company at a salary of $15 a day for every day in the year. Samuel Stanley and Thomas Cannon, both Seattle men, are members of the board of directors. The company was incorporated with $75,000 capital stock in August last.

The Philadelphia "Inquirer" relates the following as showing a new use for hairpins. Rather late in the night a trolley car in which there were a number of young women very anxious to get home went bowling along Twelfth street at a good rate, when suddenly there was a flash, a slight report, and the car was in darkness. The fuse had burned out, and the outlook was very good for staying there until the next car came along, forty-five minutes later. The passengers were disgusted. A few of them got up and walked outside to cool off. The conductor was a sort of philosopher, and after making an examination of the fuse resolved on a happy idea. "Now," he confided to one of the passengers, "if I can only get some of those women's hairpins I'll have this fixed up in a jiffy." And with this he went in and explained the case to the female passengers. At first they giggled, but after having their little fun they produced the pins. "You see," said the Knight of the Strap, "I can connect the two poles of the battery with hairpins, which will make the circuit, being good conductors, and it will answer pretty well." In a few seconds he had repaired the break and the car was speeding down the street as if nothing had happened.

COMMERCIAL PARAGRAPHS.

The Electric Appliance Company, Chicago, have just placed in the printer's hands copy for their new telephone catalogue. They claim that this will be the best all-around telephone apparatus and supply catalogue that has so far been issued. It will be ready for distribution in the course of a few weeks, and telephone companies are advised to send in their applications now so that their names may be placed on file and the catalogue may be sent as soon as it comes from the press.

The Goubert Manufacturing Company of New York City, manufacturers of the Goubert Feed-Water Heater, state that they are at present exceedingly busy. The magnitude of modern steam plants is well exemplified by the fact that they have just booked the following orders:

One 8,000 horse-power heater for one of the New York & Pennsylvania Company's pulp mills.

One 3,000 horse-power heater for the Cleveland Railway Company, Cleveland, O.

One 5,000 horse-power auxiliary heater for the Metropolitan Street Railway Company of New York City, making 35,000 horse-power now building for that company alone.

They have also just delivered a 3,000 horse-power heater to the People's Electric Light Company of Newark, N. J.

These orders, in addition to regular calls for heaters of smaller sizes, among them 1,000 horse-power for the Schenectady Railway Company and 1,800 horse-power for the Citizens' Light & Power Company of Houston, Tex., are indicative of the magnitude of the business done by the Goubert Company.

A "Morse Watch" or Secret Telegraph Sounder.

In this issue we introduce our readers to a new telegraph instrument known as the "Morse Watch," which derives its name first from Prof. S. F. B. Morse, the father of electric telegraphy, after whom the American system of telegraphy takes its name "Morse," and second from its strong likeness in its outer form to a pocket timepiece. It consists of a transmitting and receiving telegraph instrument, a key and a sounder, both of which are enclosed in a regular pocket watch case; this type of instrument is known to the telegraph craft under the general title of "secret sounder."

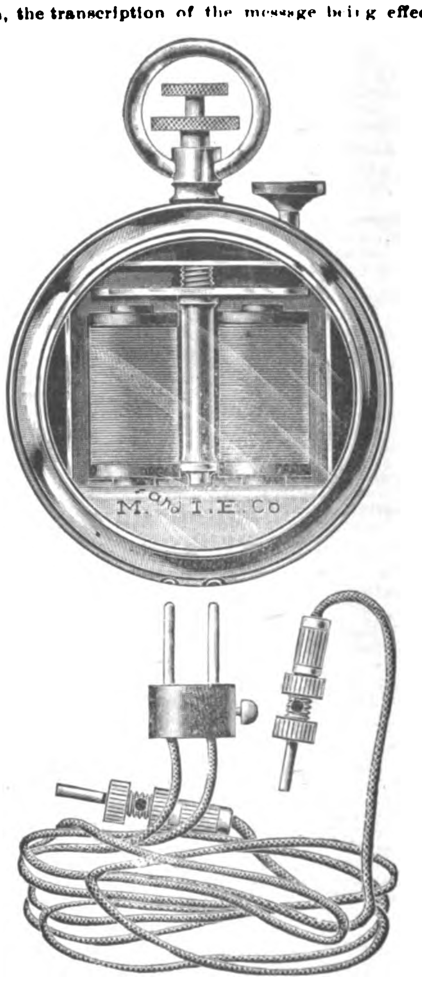
The secret sounder bids fair to play an important part in the telegraph industry of the world. Its precise object is to secure secrecy, portability and immunity from noise.

The Morse Watch is a pioneer instrument in its class. Heretofore some attempts have been made to produce a secret sounder with results more or less satisfactory, but it has remained for the Manufacturers & Inventors' Electric Company of New York to produce the first perfect instrument of the kind, indeed the only one that combines a telegraph key with the sounder. The Morse Watch is so constructed that the click of the instrument can be adjusted loud enough to be heard in any part of a comparatively large room, or be adjusted to a point where the click is inaudible unless the instrument is held in contact with the ear.

The Morse Watch is accompanied with a suitable flexible head band to fasten the instrument in place on the head over the ear, leaving both hands free for transcribing messages or other work. It also has a very neat silk conducting cord with specially designed terminals so that the instrument can be conveniently and quickly attached to or disconnected from the ordinary instrument of a telegraph line.

The employment of the art of telegraphing has so far developed at the present time that the telegraph operator is found in one corner of many brokers' as well as newspaper offices, police stations, etc., and in such places it is desired to maintain for the transaction of other business as much quiet as possible. The Morse Watch secures that end by permitting the telegraphing to go on to all intents and purposes in perfect silence, and as secrecy is often an imperative condition the Morse Watch subscribes to this requirement in the fullest measure by protecting the signals from the hearing of all persons except the operator to whose head the Morse Watch is attached.

Our readers may have often remarked that in later years their telegrams come to them transcribed by typewriters, but it is not generally known that the manipulator of the typewriter and the telegraph operator is one and the same person, the transcription of the message being effected



THE MORSE WATCH.

upon the typewriter simultaneously with its receipt from the telegraph sounder, and owing to the fact that the typewriter is a comparatively noisy machine it becomes necessary for the operator to have an instrument which by being brought close to the ear has an advantage over all other sounds and enables the operator thereby to continue his work uninterruptedly despite any noise or confusion that may surround him, and it is perhaps right here more than anywhere else that the Morse Watch will find its most extended use.

Probably the most important use however that the Morse Watch will serve is in connection with the military telegraphs and all offices where absolute secrecy is one of the first requirements.

Less confidence will not be accorded the practicability of the new invention when it is known that the destinies of the manufacturing concern are presided over by Mr. T. J. Smith, who for so many years was manager of The E. S. Greeley & Co., and is also himself an old-time practical telegraph operator.

Any further information regarding this interesting and useful invention can be secured by addressing the Manufacturers & Inventors' Electric Company, 96 and 98 Fulton street, New York City.

INCORPORATIONS

The Atwood Power & Speed Gage Company, Newark, N. J.—to manufacture electrical and steam measuring instruments. Capital stock, $75,000. Incorporators: George F. Atwood, Orange, N. J.; Harry A. Fields, New York City; George R. Swain, Newark, N. J.

The Portland & Camden Railroad Company, Portland, Ind.—to build and operate an electric railway between

Portland and Camden. Capital stock, $50,000. Incorporators: Frank S. Vine, James Droege and others.

The Metropolitan Electrical Supply Company, Chicago—to manufacture and deal in electrical supplies. Capital stock, $15,000. Incorporators: William H. McKinlock, Walter E. McKinlock and George Dickinson.

ELECTRICAL PATENT RECORD.

Letters Patent Issued October 4, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

611,752. Trolley-Ear. Henry Geisenhoner, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed July 15, 1898.
611,760. Surface-Contact Railway System. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Nov. 29, 1897.
611,778. Electric Railway. Justus B. Entz, Philadelphia, Pa. Filed Dec. 21, 1895.
611,821. Electric-Railway Conduit and Trolley. John H. Robertson, New York City. Filed Oct. 20, 1896.
611,677. Car-Fender. William C. Collyer and William F. Bullock, Lynn, Mass. Filed Dec. 8, 1897.

ELECTRIC LIGHTS AND APPLIANCES.

611,601. Electric-Arc Lamp. Sigmund Bergmann, New York City, assignor to the General Incandescent Arc Light Company of New York. Filed July 10, 1897.
611,766. Device for Suspending Arc-Lamps. Joseph Borka, Buffalo, N. Y. Filed March 4, 1898.

ELECTRICAL MEASURING INSTRUMENTS.

611,722. Electrical Measuring Instrument. Edward Weston, Newark, N. J. Filed Jan. 10, 1898.
611,723. Index Needle or Hand for Electrical Measuring Instruments. Edward Weston, Newark, N. J. Filed Jan. 10, 1898.
611,721. Electrometer. Edward Weston, Newark, N. J. Filed Feb. 14, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

611,719. Electrical Circuit Controller. Nikola Tesla, New York City. Filed Dec. 10, 1897.
611,809 Electric Meter. Sydney Evershed, London, England. Filed Dec. 21, 1897.
611,850 Electromagnetic Engine. Peter B. Watson, Philadelphia, Pa., assignor to Robert M. Robinson, same place. Filed May 9, 1898.
611,869. Automatic Switch Apparatus. Alfred Schlatter, Buda-Pesth, Austria-Hungary. Filed Sept. 21, 1897.
611,902. Apparatus for Adjusting Phases of Alternating Currents. Johannes H. F. Gorges, Berlin, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Dec. 27, 1897.
611,927. Multiple-Rate Metering System. Frederick T. McIntyre, Washington, D. C. Filed March 25, 1898.
611,970. Method of and Means for Controlling Energy Delivered to Translating Devices. Harry W. Leonard, East Orange, N. J. Filed Jan. 21, 1896.
611,996. Apparatus for Cleaning Ships' Plates. Warren P. Freeman, New York City. Filed June 30, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

611,919. Telegraph-Key. Frank E. Lewis, Jefferson, Tex. Filed Dec. 2, 1897.
611,974. Automatic Switching and Telephone System. Lars G. Nilson, Sioux City, Ia. Filed March 9, 1896.

SIGNALS AND SIGNALING APPARATUS.

611,638. Signal Apparatus. Harry G. Leopold, New York City, assignor of one-half to Erwin Lavens, same place. Filed Sept. 8, 1897.
611,894. Signaling. John P. Coleman, Edgewood Park, Pa., assignor to the Union Switch & Signal Company, Swissvale, Pa. Filed Jan. 3, 1898.
611,897. Electric Signal Device for Railways. Louis T. Dube, Paris, France, assignor of one-half to R. N. Archer, Lenoir City, Tenn. Filed Dec. 6, 1897.
611,913. Railway Signaling. Jens G. Schreuder, Edgewood Park, Pa., assignor to the Union Switch & Signal Company, Swissvale, Pa. Filed Jan. 3, 1898.

MISCELLANEOUS.

611,707. Electrical Conductor. Joseph Pedriali, Brussels, Belgium. Filed March 30, 1898.
611,822. Electric Time-Switch. Frederick M. Schmidt, James H. Gerry and William S. Barstow, New York City, assignors to the Self Winding Clock Company, same place. Filed Nov. 18, 1897.
611,971. Electrical Wiremen's Combined Gage and Calculator. Herbert Lutz, Hamilton, Canada. Filed Feb. 28, 1898.
611,992. Alarm-Lock. Edward N. Case, Chicago, Ill. Filed Jan. 8, 1898.

DESIGN.

29,451. Electrical Instrument Case. Waldo A. Layman, St. Louis, Mo. Filed July 14, 1898.

TELEPHONE AND TELEGRAPH.

The Mississippi Valley Telephone Company.

We learn from St. Paul, Minn., papers that a bill of sale was filed in the office of the Register of Deeds in that city on September 30 by which the Mississippi Valley Telephone Company transfers to the J. C. Hubinger Company of Keokuk all of the franchise rights, real and personal property belonging to the telephone company. The sale is in blanket form and covers the franchises, plants and real estate owned by the company in the States of Iowa and Minnesota, including the franchises granted by the cities of St. Paul, Minneapolis, Fort Madison, Burlington and Muscatine, Ia. The consideration does not appear in the bill of sale, this being covered by the words, "for value received."

In January last, J. C. Hubinger, of Keokuk, Ia., applied to the city council of St. Paul for a local telephone franchise. Objection was made, owing to the fact that there had been no incorporation, and the same objection was raised to the granting of a franchise in Minneapolis. To do away with this, Hubinger incorporated under the name of the Mississippi Valley Telephone Company. A number of prominent business men and members of the council in both St. Paul and Minneapolis interested themselves in the proposed new telephone company, and franchises were granted in both cities.

The attorneys and those who appeared in behalf of the company gave it out that J. C. Hubinger, of Keokuk, was the whole thing, as it were, and was perfectly responsible. For fear that there might be a mistake made, the ordinance was drafted with a provision that the new company should not sell or transfer its franchise "to any other telephone company" without the consent of the common council.

The bill of sale is signed by Hubinger as president, and D. R. Craig secretary, of the Mississippi Valley Company. The document is dated at Keokuk, Sept. 17.

Since the ordinance granting the franchise passed the council, considerable work in the construction of the system has been done in St. Paul as well as in Minneapolis.

Conduits have been laid in the business district, and resolutions allowing the company to erect poles and string wires in various parts of the city have been passed by the council.

The fight against the Cumberland Telephone & Telegraph Company has been renewed in the Chancery Court at Memphis, Tenn. The suit was brought by citizens of Memphis and Brownsville to enforce an equal rate of charge for telephones in the State of Tennessee and for damages growing out of alleged illegal discrimination. The rates made by the Cumberland Telephone & Telegraph Company differ widely throughout the State, and the price paid for the use of a telephone for one month in one place, it is alleged, will be sufficient to pay the rent on a similar telephone in another place for a year. In comparing the two towns, Columbia and Brownsville, complainants say that Brownsville has a population of over 3,500 inhabitants and that there is no such difference in the situations of the citizens of Columbia and those of Brownsville as to justify a higher charge in the latter place than the former, and that while 50 cents is charged in Columbia, $1.50 is charged in Brownsville, notwithstanding the obligation imposed upon it by law to furnish all applicants without partiality or discrimination.

In Waterloo, Ia., we learn from a dispatch in the Cedar Rapids *Republican*, trouble has arisen between the city officials and the Cedar Valley Telephone Company, and as a result the company has been ordered to remove its telephones from all the city buildings. The city officials claim that when the company asked for a franchise it agreed that should the request be granted it would furnish all the city telephones free of cost. The franchise was granted, the officials say, but from the first the company has been sending in bills every month and the bills have, after much discussion, been allowed. When the September bill was presented the patience of the council had reached its limit, and a resolution was passed ordering the company to remove its 'phones from all the city buildings.

The San Francisco *Examiner* states that the Pacific Telephone & Telegraph Company has notified the Supervisors of San Francisco that the chief of police is using telephones which infringe upon the Berliner patent possessed by that company, and if their use is persisted in legal steps will be taken to protect the patent rights. At a meeting of the Supervisors' judiciary committee the matter was discussed and referred to the City and County Attorney for his opinion as to the proper action to be taken by the board.

In the Circuit Court at Alexandria, Va., a decree has been entered by Judge Nicol, ordering a sale of the personal property, fixtures, lines, etc., of the Home Telephone Company. John M. Johnson and A. W. Armstrong were appointed commissioners to conduct the sale. The sale was ordered on the application of Douglass Gordon of Baltimore, who holds a large block of the company's stock. The affairs of the company have been in the hands of the courts for some time. In addition to the local service afforded by the Home Company in Alexandria it has operated the Janney line, which connects Alexandria, Fairfax Courthouse, Centerville, Wellington, Manassas, Haymarket and Waverley. The Janney line is in no way affected by the order of the court, and it is said that the sale of the property of the Home Company will be delayed for some time.

The Valley Telephone Company filed at Saginaw, Mich., on the 3d inst. a mortgage covering the issue of $70,000 worth of bonds, issued for the improvement and further construction of the plant. The mortgage runs to Thomas Cranage as trustee. The bonds are dated September 1, and are to be paid in annual installments of $10,000 each, beginning September 1, 1901. They bear 5 per cent. interest and were sold at par.

Capt. Brady of the United States Signal Service has been ordered to begin the construction of an overland telegraph line 320 miles in length from Guantanamo via Santiago de Cuba to Manzanillo. The line is to be used principally for the transmission of Government dispatches, although commercial messages will be accepted. The present cost of transmission of messages by telegraph from Guantanamo to Santiago is 20 cents a word up to thirty words and 12 cents for each additional word.

The Nebraska Telephone Company has a large force of men at work building a line from Seward to Columbus, Neb. This when completed will give that part of the State direct communication with Lincoln. It is the intention, as soon as the line reaches Columbus, to build on west to Grand Island via Genoa and Fullerton, establishing several new telephone exchanges and making Columbus quite a central point.

A telephone decision just rendered by Judge Coolidge of the Circuit Court at Benton Harbor, Mich., will interest all Michigan cities that are in controversy with the Bell Company. The Bell applied for a mandamus to compel the city to grant it permission to set poles and string wires in the streets. The city offered to give a franchise the same as enjoyed by the other telephone company, but the monopoly would not accept it. The court decides that the position of the city is correct.

At Columbus, O., on the 5th inst., the Supreme Court overruled a motion by the Central Union Telephone Company for the dismissal of the suit in mandamus brought by Auditor of State Guilbert against the County Auditor of Franklin county to compel him to list telephone boxes at their true value, rather than at their tangible value, and the case will now be heard on its merits.

A new telephone line is to be established between Smithfield and Suffolk, Va., via Isle of Wight Courthouse. The stock has been subscribed for in Isle of Wight county, and the purpose of the company is stated to be, not to make money, but to build and operate the line from motives of public spirit alone. It will probably be well patronized.

The American Bell Telephone Company's statement of output and return of instruments for the month ended September 20 shows: Gross output, 31,977, increase over the same month in 1897, 12,779; returned, 12,931, increase 5,826; net output, 19,046, increase 6,953. Total outstanding September 20, 1,055,586; increase over 1897, 189,322.

The Southern Bell Telephone Company has just completed the installation of a new switchboard of 1,500 capacity at its exchange in Macon, Ga. It is similar to the one at Atlanta.

Jesse H Walton, a well-known Pennsylvania Railroad telegraph operator, was struck by an engine near Greensburg, Pa., on the 3d inst. and instantly killed. He was 25 years old and married.

Ben A. Neal and Clark Grier have obtained a franchise and will construct a telephone system in Washington, Ga.

New Companies Incorporated.

The Urbana Telephone Company, Urbana, Ohio. Capital stock, $30,000. Incorporators: D. B. McDonald, Edward L. Barber, James S. Bradley, Jr., J. H. Dimond and others.

The Grafton Telephone Company, Grafton, W. Va.—Capital stock authorized, $10,000; subscribed, $900; paid in, $90.

The Seneca Telephone Company, Seneca, Kan.—to maintain and operate a telephone line in Seneca and neighboring places. Capital stock, $5,000. Directors: R. M. Emery, J. H. Glascow, J. T. Campbell, A. R. Spaulding, M. R. Connet and J. H. Hatch, all of Seneca.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12¼c.; Lake, 12⅜@12½c; casting, 11⅞@12c.

The Quincy Street Railway Company of Quincy, Ill., has filed a mortgage for $500,000 in favor of the Portland Trust Company to secure an issue of bonds for the same amount.

The United Electric Securities Company, Boston, has retired $20,000 of its 5 per cent. collateral trust bonds, 8th series, at an average price of 102.925, leaving $236,000 still outstanding.

The Board of Control of Cleveland, O., adopted a resolution on the 7th inst. that insures a four-cent car fare on two of the principal lines and ultimately on all of the street car lines in Cleveland.

The Kings County Elevated Railroad Company of Brooklyn has ten of its new cars electrically equipped, and in a few weeks will begin carrying passengers across the bridge on electric cars.

Business men of Davenport, Rock Island and Moline, Ia., have purchased a controlling interest in the Tri-City Railway Company at Davenport from its Chicago owners, the purchase price amounting to between $300,000 and $400,000.

The Union Switch & Signal Company, a Westinghouse concern, has absorbed the National Switch & Signal Company of Easton, Pa. The stockholders will meet December 13 to vote on an issue of $500,000 5 per cent. gold bonds to pay for the purchase.

The Southern Electric Light & Power Company of Philadelphia, the only one not owned by the Pennsylvania Manufacturing, Light & Power Company, will on November 23 vote on the question of increasing its capital stock from $400,000 to $2,000,000.

A special meeting of the stockholders of the New York & New Jersey Telephone Company will be held in Brooklyn, N. Y., October 27 to vote upon a proposition to increase the company's capital stock from $5,000,000 to $8,000,000. The proceeds will be applied to extensions and the new stock will be offered to stockholders at par.

The American Railway Electric Light Company has elected the following directors: Alonzo B. Cornell, Edward Valk, Wilbur Huntington, H. Livingston Rogers and H. J. Carr of New York, and Fred J. Haerer, A. N. Chandler, George W. Crosscup and A. G. Fromuth of Philadelphia. The president of the company will be elected this week.

A syndicate of New York capitalists is reported to be negotiating for the purchase of the Sandusky, Milan & Norwalk Electric Railway and the People's City line of Sandusky, O. The transaction is said to be the first step in a plan to build electric railways, connecting a large number of Northern Ohio cities and towns with Cleveland.

Justice Childs has granted to the Commercial National Bank of Cleveland an injunction restraining the Syracuse (N. Y.) Rapid Transit Railway Company from borrowing $23,000. The charge is that certain directors are interested in the deal and that it will cost $30,000 in commissions and $70,000 in preferred stock to perfect the loan. The case will be fought in the courts.

An installment of $5 per share has been called by the directors of the Union Traction Company of Philadelphia, payable on or before November 16 at the transfer office of the company, 423 Walnut street, Philadelphia. Transfer books will close November 15 and reopen November 17. Upon the opening of the transfer books no transfer will be made of any certificate upon which the payment of this installment has not been endorsed.

The directors of the Brooklyn (N. Y.) Elevated Railroad Company have decided to begin proceedings for the discharge of the receiver of the property. The reorganization of the company is now practically accomplished, and the formal sale under foreclosure can be made in about thirty days. A purchasing committee has been appointed which will buy the property in for the security holders, unless some bidder appears who will pay more than $30,000,000 for the same. The name of the reorganized company will be the Brooklyn Union Elevated Railroad Company.

The directors of the Columbia Railway Company, Washington, D. C., have decided to equip that part of their road between the Treasury and 15th street east with the underground trolley. In order to meet the estimated cost of the change of motive power, the acquisition of the right of way for proposed extensions and the cost of construction and equipment of the entire line, which will be a total of about seven miles in length, the stockholders have authorized the issue of $500,000 of 5 per cent. gold bonds, payable in 1914, secured by deed of trust on all the property and franchises of the company.

The New Orleans Traction reorganization plan creates a new company to own all the property of the old company. They will issue $3,000,000 new bonds, $2,500,000 new preferred and $500000 new common, which, together with $3,141,800 undisturbed bonds, makes the total bonded debt of the new company $6,141,800, and annual requirements for taxes and charges $380,013. The stockholders are not pleased with the reorganization scheme, as it seems to promise that small owners of collateral trust notes get an equal amount of new common, but old common holders get only 22½ per cent. of new and have to pay $3 per share assessment.

For the purpose of paying its floating debt incurred in the acquisition of the securities of other street railways, and for changing the motive power of its lines, the directors of the Third Avenue Railroad Company, New York, have decided, it is announced, "to issue stock from time to time instead of issuing bonds. Two millions of stock now in the treasury, and long since authorized to be issued, is now being issued, and further issues will be made in all probability from time to time, as additional money will be required. The amount required for improvements will not be more than $15,000,000, and the total amount of stock issued in any event will not exceed $35,000,000. A consolidation between the present Third Avenue road and some of its affiliated companies is being considered, and if carried out the additional stock will be that of the consolidated company."

The deal by which the Brooklyn Rapid Transit Company was to gain control of the Nassau Electric Railroad in Brooklyn, N. Y., appears to have fallen through. The Brooklyn "Eagle" of the 9th inst., referring to the deal, says: "The Johnsons have fixed par as the price of their common stock. Flynn has refused to sell at 80 for his preferred and common shares. The option to buy the Wilson stock expires on November 3. Up to the present time the Transit people have not purchased it. If they buy it without first getting the stock held by the Johnsons or by Flynn, they can do but little with the property to advance the market value of Rapid Transit, which is, of course, their only object. President Johnson of the Nassau Company is going to Europe next Saturday and does not expect to find any change in the situation when he returns in the next six weeks."

"It is now reported," says the N. Y. "News Bureau," "that the New York Gas and Electric Light, Heat & Power Company, recently incorporated with a capital of $25,000,000, is about to absorb the Block Electric Light & Power Company. The latter is a small corporation with a capital of $200,000, whose operations are confined to a few squares near the Grand Hotel, in the basement of which it has a small plant. The Block Company was chartered in 1894, and its franchise is said to be a very liberal one, unaffected by the twenty-five years limitation, included in the new city charter, limiting the life of corporations. It is understood that the Block Company was purchased last January by former Lieutenant-Governor William F. Sheehan, and that he is interested in the new $25,000,000 company which is to absorb the rights and franchise of the little corporation."

ELECTRICITY.

Vol. XV. NEW YORK, OCTOBER 19, 1898. No. 16.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 1081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	2.00
FOREIGN COUNTRIES,	4.50
SINGLE COPIES,	10 cents

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The People's Telephone Company.

At stated intervals during the past five years the people of New York City have had their hopes buoyed up by announcements of the formation of new telephone companies to compete against the Bell monopoly as represented by the New York Telephone Company. Legislative action having repeatedly failed to bring about a reduction in telephone rates in this city, apparently the only hope for relief lay in the organization of a new concern sufficiently powerful to endanger the interests of the existing company. As just stated, several telephone companies have been started from time to time with this laudable object in view, only to subsequently quietly disappear from the telephone horizon and with them all hopes of relief for the time being at least.

About a year ago there was considerable talk of a new company which it was said was about to be formed to compete with the New York Telephone Company in Greater New York. This company was to be known as the Citizens' Telephone Company, and was said to be an offspring of the company of the same name then successfully operating in Detroit. After attracting considerable attention, as has been usual in such cases, no developments followed, and the general public again relapsed into a state of resignation while awaiting some new appearance in the telephone field in this city. It now seems possible that the patience of the long-suffering telephone users in the metropolis is about to be rewarded. On October 12 there was incorporated at Albany what is known as the People's Telephone Company with a capitalization of $5,000,000.

That the incorporators of this concern are in earnest cannot be doubted, as an organization tax of $6,250 has already been paid, and the fact that a number of wealthy men, among whom are several prominent members of the New York Board of Trade and Transportation, are back of the undertaking, insures, if not its success, at least that a determined effort will be made to gain a foothold in the field that has for years been monopolized exclusively by the New York Telephone Company.

Mr. Frank S. Gardner, secretary of the new company as well as secretary of the Board of Trade, has made the following statement regarding the undertaking:

"The movement is the result of fourteen years of unsuccessful opposition to the telephone monopoly that has New York in its grasp. Costly experience has shown that legislation would never give New York adequate telephone service at reasonable rates. The only way to achieve that end is to give the monopoly battle on its own ground. This the People's Company will do. We will compete in every possible way. The rate we will establish will not be more than one-half the present rate, and probably will be less."

The rates the new company proposes to charge when established will, we understand, be $100 a year for unlimited service in the Borough of Manhattan as against $240 now being asked. Limited service will be offered at the rate of $40 for 400 messages as against $90 for 600 messages now charged. The residence message rate over a private wire will be $30, while unlimited service over party lines will be offered at $12 a year. These figures would seem reasonable, and yet we venture to say they will net the stockholders a fair profit.

The apparently insurmountable difficulties met with by former telephone companies that have endeavored from time to time to gain a foothold in this city have been the procuring of subways wherein to lay cables, and also the procuring of modern central exchange apparatus that would not infringe on some of the numerous patents owned by the Bell Company. It is believed, however, that there are one or two subway franchises owned by more or less obscure concerns that could probably be purchased for a reasonable sum of money, and as the officials of the People's Telephone Company claim they are provided for in this respect, we do not doubt but what the subway difficulty has been overcome. The instruments to be used will we understand be of a new pattern only recently brought out.

Taking it all in all it looks very much at present as though in the near future cheaper rates will be obtained from the New York Telephone Company, not through an act of the Legislature, but in just as forcible a way, through competition.

* * *

A New Submarine Lamp.

An invention has recently been made which should prove of inestimable value to divers in submarine work. Heretofore in examining a wreck or the hull of a vessel under water a comparatively low candle power incandescent lamp enclosed in a heavy and watertight bulb was made use of. Now, however, it has been ascertained that it is practicable to use the arc light for this purpose. That an arc between two carbons can be maintained under water under certain conditions has been known for some time, and is an experiment not unfrequently performed in the laboratory to surprise the uninitiated and apparently demonstrate the fallacy of the old belief that fire and water could never be made to combine. Performing such an experiment and designing an arc lamp to be used many feet under water were two very different things. The problem, however, has apparently been

solved by two students taking the electrical engineering course at Yale—Irving E. Burdick and Francis G. Hall. These young men at the outbreak of the war with Spain were employed by the Government in testing and laying submarine mines in certain harbors along the coast of Maine. While thus employed the advantages of securing a more powerful light for submarine work than the ordinary incandescent lamp could furnish became apparent. After thinking the matter over, a practical method for making use of an arc light suggested itself, and they accordingly communicated with the Navy Department, explaining their idea and asking permission to experiment along that line. Owing to the prosecution of the war their request went for some time unheeded. Permission was, however, finally granted them to go ahead, which they accordingly did, all the experiments being carried on at the New York Navy Yard.

The submarine arc lamp as designed by Messrs. Burdick & Hall after considerable experimenting is an enclosed arc lamp absolutely water tight, with an inner and outer globe, the upper part of the outer globe being hermetically sealed to the metal cylinder containing the feeding mechanism by means of rubber gaskets and rings. The feeding mechanism in this lamp differs from that of the ordinary arc lamp in that it is enclosed in a cylinder both water and air tight. From the top of the cylinder through a carefully packed aperture issue the two insulated wires, which for convenience are bound together into a cable. The lower portion of the lamp is protected by an eight wire guard. Most of the tests made at the Navy Yard were at a depth of twenty-five feet, and at this depth were said to be very satisfactory. Although no attempts have as yet been made to use the lamp below this depth, there would seem little doubt, now that the principal difficulties have been overcome, but what a lamp of this nature could be made to stand any pressure corresponding to any depth at which a diver could safely operate.

The advantages to be derived by the use of a 1,000 or 2,000 candle power lamp where formerly a 32 candle power lamp was made use of are apparent. Owing to the penetrative power of its rays it should enable the taking of fairly good photographs under water, which has heretofore been a more or less difficult matter with the incandescent lamp.

* * *

The Lucigraph. There are at present a number of methods of night signaling in use on the warships of different nations. These systems are in general detail more or less similar, usually consisting of a row of three double lanterns hung from a portion of the ship's rigging or alongside the mast. Each lantern can be made to show either a red or white light, the order in which these lights are lit and extinguished corresponding to a given code. In the merchant marine so far no system of night signaling has been adopted, and even were a merchantman provided with the regulation signaling apparatus used in the navy it would be of no use unless a code were formulated and adopted by vessels of all nations. With a view to overcoming this deficiency, which is said to have been responsible for many shipwrecks and accidents in the past, Mr. John W. Haywood of St. John's, N. F., has invented an apparatus known as the lucigraph, whereby the letters of the international maritime code may be thrown on a suitable background and thus made visible at night. The principle on which the lucigraph works is practically the same as that of the magic lantern, excepting that a far more powerful light is made use of in the former than in the latter. The apparatus is fitted with a four-inch condenser and a two-inch lens. Between the two, on the side, are located a number of movable stencil plates cut to represent the letters of the alphabet and numerals from 1 to 9. Along the top of the apparatus is a keyboard fitted with a double row of keys resembling those on a typewriter. When one of these keys is pressed down the stencil plate corresponding to that key springs up between the condenser and the light, its outline being projected upon any object lying in the path of the light rays. A sheet of canvas tightly stretched has so far been made use of almost exclusively on which to throw the letters, but this background has not proved satisfactory for several reasons. On shipboard, for instance, it has been found almost an impossibility to stretch the sheet sufficiently tight to prevent its being shaken by the wind, resulting in more or less indistinct letters. Another objection raised against this form of background, and which will undoubtedly prevent the adoption of the lucigraph by the navy, is the fact that the showing of a white canvas on a man-of-war in time of hostilities would draw the fire of the enemy, resulting in the almost certain destruction of the background and the interruption of further communication.

With a view to overcoming these defects, the inventor now proposes to make use of two canvas-covered arms, somewhat resembling those of a windmill, which on being revolved at a high rate of speed would show apparently an unbroken surface on which the letters could be thrown. This proposed arrangement, although seemingly an improvement over the canvas sheet, still has objectionable features which would probably cause it to be adopted on shipboard but slowly. The funnels of a ship might be made use of as a background in weather not too heavy, or the reflection might be thrown on the clouds.

The distance at which the letters can be read depends of course upon the intensity of the light used. It is estimated that a 1,000 candle power light will throw a ten-foot letter which can be made out without difficulty at sea a distance of two miles.

In August last the lucigraph was given a trial on the warship San Francisco while off Cape Cod, and although it was generally admitted the apparatus worked all right and was a success, the screen arrangement was condemned for the reason previously given. On the night of October 12 another test of the lucigraph was made at the pier of the North German Lloyd Steamship Company in Hoboken in the presence of a number of steamship companies' representatives. Letters ten feet in height were thrown upon a canvas and were readily made out, in spite of the glare emanating from the city, at a distance of considerably over a mile. So favorably impressed were those present at the results that it is thought that as soon as the background problem has been satisfactorily solved the North German Lloyd line will equip its steamers with this form of night signaling apparatus.

Under the Searchlight.

Notes and Comments on Various Topics.

A FEW nights ago the iron stairway and guard rail leading to the Park avenue tunnel at Thirty-fourth street became charged with electricity from some stray current, resulting in considerable fun for the bystanders. The first person to experience the effect of the current was a Mott street Chinaman. As the Mongolian landed on the top step and grasped the wet railing he gave a yell that echoed down the tunnel, and slid all the way to the bottom, narrowly missing losing his legs under a car which just then shot by. Shaking his fist at the "hidden devil" the Chinaman picked himself up and took the next car. The second victim was a policeman. He took the toboggan with a leap and a jump. A group of people returning from an entertainment were then caught. With a scream men and women went down together. By this time so large a crowd had gathered to watch the fun that the cars were blocked and a policeman had to be called to clear the tracks and prevent further descents until the cause of the disturbance was removed.

* * *

The Westinghouse Company's Last Balance Sheet.

The following appears in the Boston *Herald* of the 11th inst.:

The balance sheet of the Westinghouse Electric & Manufacturing Company as of July 31, 1898, transpires through the listing department of the New York Stock Exchange, and is:

ASSETS.

Cash	$152,732
Bills receivable	115,596
Accounts receivable	2,157,795
Material in stock	1,872,019
Sawyer Man Electric Company	783,253
Real estate, etc	1,519,557
Machinery, tools, etc	1,374,542
Stocks and bonds	5,846,086
Patents, charters, etc	4,763,785
Miscellaneous	354,019
Total assets	$18,951,384

LIABILITIES.

Accounts payable	$559,698
Bills payable	2,741,894
Dividend scrip	194,560
U. S. Electric Light Company bonds	800,000
Collateral Trust bonds	590,000
Preferred stock	3,996,750
Assenting stock	8,227,475
Common stock	146,700
Surplus	2,191,322
Total liabilities	$18,951,384

The item of bills payable is a pretty large one, but cannot be properly valued without more knowledge than is conveyed by a transcript of ledger balances. Some day the company may find it convenient to issue an annual report to the shareholders—some day, when a favor is wanted or there is some end to serve out of the usual order.

* * *

AN amusing incident, says *Electricity*, London, occurred the other day at Leicester. The chairman of the Electric Lighting Committee was just presenting the report of the department for the past half year, and commenting upon the improvement which had taken place, when, for some reason, the room, which was lit with the electric light, was placed in darkness, and gas had to be resorted to.

* * *

IN addition to the immediate consequences of the organization of the People's Telephone Company as affecting the telephone business in New York, its creation must have a beneficial effect as a warning to other mammoth corporations that men and means can always be found to obstruct the aims of those who seek to monopolize trade or take unjust advantage of their opportunities.

* * *

MISS CARRIE PRIEST, the belle of Wintersville, O., a few days ago defeated the intentions of the Phoenix Telephone linemen to place a pole in front of the Priest residence. When the hole was partly dug Miss Priest discovered what they were doing, seized a chair and placed it over the place, sat on the chair and could not be induced to move. The telephone men were compelled to place the hole in another spot.

* * *

THE Paris Exposition commission at Chicago has received a cablegram from Commissioner-General Peck, now in Paris, saying that after extended negotiations the Paris authorities had granted increased concessions of space for American exhibits in the Exposition, amounting in a number of departments to 25 per cent.

* * *

THE rivalry between the Postal Telegraph Company and the Western Union Telegraph Company at Fire Island promises extraordinary results in observatory construction. One has been trying to beat the other on sighting ships first and various devices have been used to accomplish this. The Postal

Telegraph Company has a very high observatory east of the Western Union tower and this gave Observer Young, of the Postal Company, an advantage over Observer Temple, of the Western Union, for the position of the Postal made it possible to see incoming vessels first. The Western Union to overcome this disadvantage is raising its tower thirty-five feet, and when the improvement is completed Observer Temple will be able to catch sight of a steamer as quick if not quicker than his rival. It is reported that the Postal Company will also increase the height of its observatory so that Operator Young will again have the advantage.

* * *

THE St. Louis *Republic* states that rats are playing havoc with the underground cables of the Bell and Kinloch telegraph companies in that city. They have discovered that the wires are covered with paraffined paper, and they rather like the taste. To satisfy their appetites they must gnaw through the lead casing around the wires. It has happened in a number of cases that the rats in gnawing through the lead cables, to get at the greased paper, have bared the copper wires so that they touch each other and cross in such a manner as to make it impossible to establish communication over them. Every time this happens it costs the company whose wires are interrupted all the way from a few dollars to several hundred. The telephone men are trying to devise some means of stopping the depredations.

* * *

A NEW switchboard will shortly be tried by the New York Telephone Company which should do away with many of the inconveniences now experienced, and incidentally make the life of the telephone girl a burden by giving her absolutely no excuse to talk. In the new device the removal of the receiver from its hook lights a tiny electric lamp by the side of the telephone number on the switchboard. When the connection asked for has been made, another lamp is automatically lit which remains lighted until the conversation is ended and the receiver returned to its hook. Thus the "hello girl" will have no excuse to break in on the conversation every few minutes to ask if you are through.

* * *

THE Salt Lake City *News* of the 4th inst. relates the following: "A mile and a half from Hooper station, on the line of the Deseret Telegraph Company, during the electric storm Sunday morning, the lightning played some queer freaks with the telegraph wire, knocking down some thirty-five yards of it, and chopping it literally to pieces. The head lineman, Mr. Carr, of the Deseret Company came to the *News* office last evening with a sack of the wire, which was broken into pieces from a half inch up to several feet in length, most of the pieces being about an inch long. Some of the pieces were found sticking upright in the ground; these were melted at the end that was in the ground, forming a bulk of fused metal. In other instances two pieces of wire had come in contact at the instant of the breaking up, and these were firmly welded together. Another strange fact is that some of the pieces of wire were twisted out of shape, but all were straight as if they had been clipped off by the means of nippers; the ends of all of them, however, were slightly fused. A handful of the wire was taken to Dr. Talmage of the University of Utah and he promptly pronounced it as being one of the strangest freaks of atmospheric electricity he had ever seen."

* * *

THE following, taken from *Industries and Iron*, London, should serve to comfort the residents of the borough of Brooklyn: "Life does not appear to be quite so valuable in Egypt as it is here; at least, they do not set so much value on it as they do in England. During the first week of the running of the Cairo electric cars eighty persons were killed by them, and since then six or seven weekly. The causes are that the Cairenes are mostly deaf or partially blind, and further, that the cars only stop at appointed stations."

Electric Advertising.

An enterprising electrician in Brussels has found the means to combine the attractive with the useful in the way of advertising, and is drawing great crowds nightly in the Place de Brouchère in the heart of the city. He displays advertisements on a screen fixed outside the third-story window of a house on the square. The advertisements are interspersed with cinematograph pictures, and as the waiting public is not provided with a programme, and can, therefore, not tell whether the next picture will be an advertisement or a free entertainment, the former receive more attention than would be the case if they were exhibited by themselves.

A National Credit Association.

The delegates of the various Credit Associations met at the Burnett House in Cincinnati on the 9th inst., and formed the National Credit Association. A constitution and by-laws governing the business policy of the new association were adopted.

The Board of Managers consists of one member of each local society, and it is the purpose of the National Society to issue a monthly list of delinquents and furnish such other important information as may be of interest to its various members. The chairman of the New York Electrical Trades Society, Mr. R. E. Gallaher, informs us that it is the purpose of the organization to establish a credit bureau through which they hope to be able to keep members posted as to all buyers of electrical goods.

THE ACTION OF ELECTRICITY ON PLANTS.*

BY E. H. COOK, D.SC., F.I.C.

The destructive effects of electricity of high potential upon plants needs no demonstration. It is only necessary to remember the wrecks which are made of our finest forest trees by a single flash of lightning to call vividly to mind the enormous power of the discharge. But the action of smaller quantities at lower potentials has not been extensively studied. True it is that from time to time we hear of wonderful results being obtained, and marvelous experiments being made. In many of these cases, undoubtedly, exaggeration has been indulged in, and the attitude of the scientific man has become very much that of the skeptic. This is unfortunate, because there is undoubtedly something in the subject, although the unraveling of the facts is surrounded by peculiar difficulties, involving complicated and extremely prolonged experimentation.

For some considerable time the idea that electricity might have more or less influence on the growth of plants seems to have been simmering in the minds of many experimenters. Thus, in 1806, the great botanist, de Candolle, experimented for a long time, but without arriving at definite results. Other experimenters also tried, but no results seem to have been obtained until Naudin used means for supplying electricity from an external source to the soil in which the plants were growing. He claims to have obtained increased effects. The experiments of Sir William Siemens with the electric light are well known, but some of the most important have been made in Russia by Spechnew, and in France by several agriculturists, of whom, perhaps, M. Barrat and M. Paulin may be mentioned. In these cases the experiments have been made on the large scale, and have extended over many years.

The experiments recorded in this paper were commenced so far back as 1886. They have been repeated many times as the conditions affecting the results gradually became known. They may be considered under three heads: (1) Those relating to the germination of seeds; (2) those relating to the growing of plants in soil; (3) those dealing with the lower forms of plant life such as algæ, fungi, etc.

1. *Influence on the Germination of Seeds.*—Numerous experiments were made in order to see if any effects could be obtained with constant or intermittent currents and with high or low tension electricity. Taking one mode of experimenting as a type of the whole, a current of electricity varying from 1 to 10 milliamperes was passed by means of carbon plates through moistened grains either of barley, wheat, peas, or other seeds contained in beakers. Side by side with these were placed similar seeds through which no current was passed. The current was switched on for about two hours daily. The results were sometimes indefinite, sometimes extraordinarily successful, but the general effect was to give an increased development in the electric seeds amounting to from 10 to 20 per cent. more than in the non-electrified ones.

Experiments were also made with a view of discovering whether constant or intermittent currents were best suited to accelerate the growth. It was found that no advantage could be obtained by constant currents over intermittent ones, and in some cases the constant current was not beneficial.

High-tension electricity was tried by subjecting the seeds to electrification from a Wimshurst machine inside glass vessels before planting. The results obtained showed that in this way a *larger proportion of seeds germinated*, but the electrified show no increased growth over the non-electrified.

2. *Influence on Growing Plants.*—The experiments on seeds showed that with a suitable amount of electricity at a suitable EMF. the germination was accelerated; it then became necessary to determine whether, after the plant was formed, any increase in the rate of the processes of assimilation and absorption took place. For this purpose experiments were tried with seeds planted in similar soil and in similar pots. Through some of these a current was sent between carbon electrodes, while the others were allowed to grow in an ordinary manner. Experiments were tried with intermittent and continuous currents, and with a variety of seeds. In almost every case the electrically urged plants came to maturity first, but they were also the first to show above the soil, and I could not satisfy myself that, with the currents employed, viz., from 1 to 30 milliamperes, and with an EMF. of 5 to 25 volts, any increased rate of growth was observable after the cotyledons appeared above the soil. In other words, an electrically urged plant grown from seed in soil will show above the soil, say, four days before one not so urged; but after that the electrically-urged plant will maintain its four days' start throughout—it will not gain after the first start. Therefore, practically, in growing plants in this way, no advantage is obtained by continuing the application of the electricity after the first appearance of the green leaves. This, of course, applies to electricity of low EMF.

Experiments were now tried to find if the same peculiarity held for electricity of high EMF. For this purpose the discharges from the Wimshurst and from the induction coil were employed. Moreover, the effects of the positive and negative were tried separately. The results showed that with the machine a much increased rate of growth is obtained when the EMF. varies from 25 to 40,000 volts; moreover, that the positive always produced the greater effect *at first*, but that the negative rapidly caught up and took the lead. It was also noticed that with

*Abstract of a paper read before the British Association, Section A.

this kind of electricity certain kinds of plants, such as bulbs, could be accelerated which could not be influenced by the current. In one of these experiments on hyacinths, the color of the blossom produced under the negative was distinctly different from that of the positive, as well as from that of the non-electrified. Possibly this may be caused by the larger amount of ozone produced by the negative discharge.

In order to compare the effects of the battery, the induction coil and the machine, experiments were made with the same seeds grown, (1) without any electricity, (2) with a current passing between carbon electrodes, (3) under the positive point from a Wimshurst machine, (4) under the negative from the same, (5) under the positive point of an induction coil, and (6) under the negative point of an induction coil. *In every case the positive end of the coil produced the greatest effect.* This was with an EMF. of approximately 45,000 volts.

Experiments with Low Forms of Plant Life.—Experiments have been made with yeast, spirogyra and other large-celled fresh-water algæ.

With yeast the rate of development was measured by the rate of evolution of the carbon dioxide. With this substance (yeast), only the current from the battery has been tried as yet. The results were somewhat indefinite, but an increased effect was produced within a very limited range of EMF. and quantity. The complete conditions regulating the growth have not been fully stated, but are still under examination.

The effect upon spirogyra was tried with the current, and with positive and negative spraying from the coil and machine. Microscopic examination was continually made in order to see if any alteration could be observed in the end cell of the filament, and also if the process of conjugation was hastened. No definite conclusions could be reached in reference to either. In some instances it was thought that accelerated growth was produced, but repetition of the experiment failed to confirm the results.

In the case of the current, electrolytic effects took place, gases being evolved from the platinum electrodes.

Great care had to be taken in the spraying with the electricity from the machines, because the fibers of the plants were found to be readily broken up at the junction of the cells, and it was difficult when this occurred to judge of the change in growth of the fibers. It is intended to continue these experiments.

Application on a Large Scale.—Experiments have been made by M. Barrat and M. Spechnew by connecting large plates of copper and zinc sunk in the soil with a wire, and growing plants between, and also by connecting plates to a battery. It is, however, evident that if atmospheric electricity could be employed, a practically unlimited source is available. Beckeinstener was the first to try this. Following him, several experimenters in France and other countries have invented, perfected and used what has been called the "Géomagnétifère," with remarkable results. The instrument is practically a lightning conductor set up in the middle of a field, and connected below with a series of cross wires running under the soil near the roots of the plants.

The results obtained with this instrument are remarkable. Thus, to quote two well-authenticated experiments: A "Geo" was set up in a field adjoining the main road from Montbrison to Montroud, of 8.5 meters high, and made its influence felt over a circular area of 20 meters radius. Within this area were marked out two squares of 4 meters side, and the potatoes growing in these patches were compared with those growing in two equal-sized patches in another portion of the same field. The potatoes grown in the two squares within the area weighed 90 kilos; those grown outside weighed 61 kilos. The number of plants were practically equal. Again, in another case, 60 potato plants grown near the wires of a "Geo" gave 63 kilos, 100 grammes of tubers, whereas 60 plants grown in the same field, but away from the "Geo," gave only 35 kilos. This gives a difference in the money value of about £8 16s. per acre. Both these experiments are well authenticated. In view of these results it was determined to make a trial in Clifton. Accordingly, in the early spring M. Pinot de Moira, who is an excellent amateur gardener as well as a scientist, was induced to put up a "Geo" in his garden on Clifton Hill. Potatoes, beans, tomatoes, peas, etc., were grown near the wires and in other parts of the garden. A distinctly increased effect was observed in all cases near the wire, thus confirming in some measure the results of the French experimenters. The crop of tomatoes is remarkable; on some plants the number of fruits is between 90 and 100, all well developed. For plants growing in the open air this is remarkable. Unfortunately, it was impracticable to grow unelectrified tomato plants to compare with these under similar conditions. It is, however, much to be desired that further and continuous experiments should be carried out.

Theories to Account for the Action.—Before attempting any theorizing, it was thought advisable to thoroughly establish the facts. Much time has, therefore, not been given to the testing of supposed explanations. One of the first ideas would be, that the rise in temperature would, perhaps, cause the effect. Very delicate thermometers plunged in the soil showed no rise in temperature; moreover, it can be calculated that, with the strongest currents employed, the rise in temperature would not exceed $\frac{1}{500}$th of a degree per hour, an amount too small to produce the effects noted.

Another theory which has been proposed by Spechnew is that a process somewhat like electrolysis goes on in the soil whereby the nutrient material is broken up into compounds which are more readily absorbed by the roots of the plants. In support of this, he cites several experiments which he has made. In confirmation in experiments made to test this, I found in the neighborhood of the positive electrode the earth was slightly acid, whereas that near the negative was faintly alkaline, thus proving the existence of an electrolytic action. But obviously this explanation will not account for many of the effects, and, in fact, the subject is so wide that many different actions are probably at work, and it will be necessary to multiply the experiments, and to know more of the conditions, before satisfactory explanations can be given. As a step in this direction, the experiments recorded in this paper are considered to show that a particular plant requires for its maximum development a distinct strength of current and of a definite potential.

THE JUNGFRAU RAILWAY.*

(Concluded from page 213.)

The power-plant at Lauterbrunnen will, when completed, utilize about 1,320 gallons of water per second from the White Lütschine, with a head of 125 ft., of which 115 ft. is utilized at the turbines. The river is swollen in the summer by the melting snow and glaciers from the mountains, and thus at the time when the greatest power is needed the most is available. A steel pipe line about 1,500 yards long serves as a head-race. It taps the river a little below the famous Staubbach waterfall, just above the railway bridge of the Wengern Alp Railway. The pipes have an internal diameter of 5 ft. 11 in. About half of the conduit is nearly horizontal, with a fall of only about 0.3 per cent.; this section of the pipe has a thickness of 0.197 in., and is made in lengths of 19 ft. 8 in. Between this and the lower half of the pipe-line a vertical pipe is attached to avoid shocks and to insure a smooth flow of water. The remainder of the line is of stouter pipe, 0.236 in. and 0.276 in. thick, the internal diameter being the same, and it is made in 24 ft. lengths. The power-house is on the right bank of the river, and the pipe-line has to cross from the left bank over an iron bridge built especially for the purpose. The upper part of the pipe line is buried, the lower part uncovered.

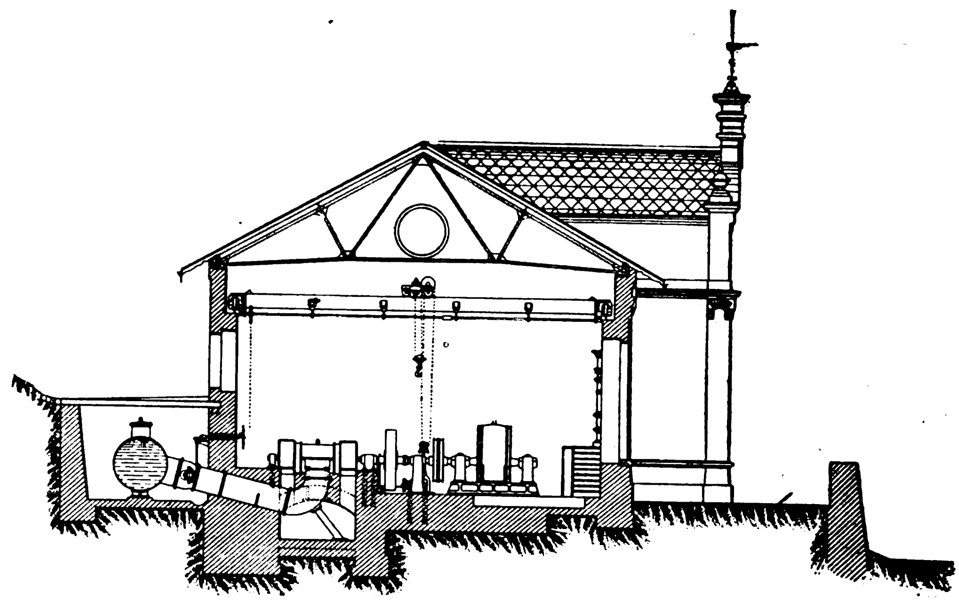

FIG. 8.—SECTIONAL ELEVATION OF POWER HOUSE, JUNGFRAU RAILWAY.

Figs. 8 and 9 show the power-house in sectional elevation and plan. It is proposed to have eventually four generating sets, each of 500 HP. capacity, but only two have been put down to start with. The turbines are of the twin Girard type, with axial flow. They work with 115 ft. head and a flow of 314 gallons of water per second at full load, making 380 revolutions per minute, the speed being controlled by Rieter's automatic governors. The generators, of the Oerlikon inductor type, are directly coupled to them. At the time of our visit the erection of the turbines had been completed, and one of the dynamos was in position, but not yet running. Power for the line and for the work in the tunnel was derived from a 1,000-HP. machine temporarily installed. The switchboard had not yet been completed either, and a temporary one was in use. The generators seem to be built on the lines usually followed by the Oerlikon Co. in their inductor type. As has been already mentioned, three-phase current at 7,000 volts and 38 revolutions per second is generated. The exciters are shunt-wound and four-polar, making 700 revolutions per minute, and generating at full load 150 amperes at 120 volts. Their turbines, which are also directly coupled to them, use 15.6 gallons of water per second. The regula-

* From the *Electrician*, London, Sept. 23.

tion of the voltage is effected by adjusting the resistance in the circuit of the exciter fields. The switchboard is on a gallery from which the whole station can be overlooked. In general appearance the station is well designed, light and roomy. We noticed to our surprise, however, that contrary to English practice, the frames of the machines were insulated from the floor instead of being earthed. This appeared to constitute a not inconsiderable danger to the *personnel*, as the distance between the bed-plates of the machines and their foundations was only about 2 in. or 2½ in. The machine that was running at its full pressure of 7,000 volts was only protected by a wooden balustrade, which it was easy to get over or under; but possibly the arrangements in this respect will be improved when the permanent plant is in running order. As a set-off to this we noticed a paper posted up, containing instructions for the treatment of persons stunned by electric shock.

In concluding this article we wish to express our thanks to Messrs. Brown, Boveri et Cie., and Messrs. J. J. Rieter et Cie. for supplying us with some of the illustrations we have reproduced, and to acknowledge the courtesy shown to our representative by Dr. Wrubel and Herr Gobat, the engineers in charge of the work, and by the other engineers connected with the various sections.

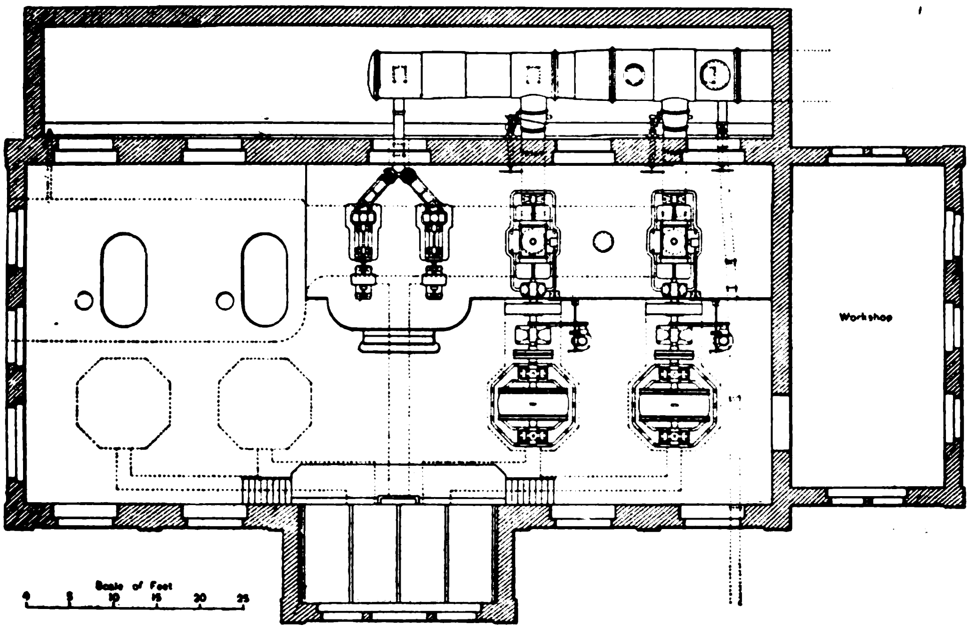

FIG. 9.—PLAN OF POWER HOUSE, JUNGFRAU RAILWAY.

A Large Electrical Pumping Installation.

There has recently been erected, at the collieries of the Arniston Coal Company, in Scotland, what is claimed to be the largest installation of electric pumping machinery in the United Kingdom. Two steam engines, of the horizontal, compound, long-stroke type, drive the dynamos, each being capable of giving 350 IHP. with 120 lb. steam pressure when working condensing. They are fitted with automatic triple expansion gear. Lancashire boilers are used working at a pressure of 140 lb. per square inch. The two continuous-current dynamos are fitted with drum bar armatures and give a total output of 200 kilowatts at 363 amperes and 550 volts. The main switchboard is so designed that the current from one or other of the dynamos, or from both combined, can be used to meet any contingency caused by the breakdown of any part of the machinery. The pumps are of the three-throw type, fitted with rams 11 in. diameter by 18 in. stroke, to deliver 500 gallons per minute against a head of 678 ft. in one case, and against a head of 256 ft., through 3,175 ft. of cast-iron pipe in another. For driving the water against the 678 ft. head, two 80 HP. electric motors are used, their speed being approximately about 450 revolutions per minute. These are coupled together, and are so constructed that the armatures are interchangeable with a single 80 HP. motor, which drives the lower lift pump. There are also three sets of smaller pumps for driving which 25 HP motors are employed.

THE DROP OF POTENTIAL AT THE CARBONS OF THE ELECTRIC ARC.*

BY MRS. AYRTON.

The carbons employed were of the same kind as those used for all my previous experiments on the arc, namely, solid "Apostle" carbons, the positive 11 mm. and the negative 9 mm. in diameter. In order to eliminate errors caused by the difference in hardness or construction of the carbons, only those were used with which it was found the P.D. between the carbons was within half a volt of that given by the equation which I published in 1895 connecting that P.D. with the length of the arc and the current flowing.

To find the fall of potential between each of the carbons and the arc a third carbon was used, varying in diameter between 0.5 mm. and 2 mm. This was brought up to the crater of the positive or the white hot spot on the negative carbon, and the P.D. between it and the main carbon was observed *just before* it touched the main carbon. The P.D. was measured by means of a high-resistance d'Arsonval galvanometer having a resistance of a million and a-half ohms in circuit.

Experiments were made with arcs of 1, 2, 3, 4, 5, 6 and 7 mm., and with currents of 4, 5, 6, 7, 8, 9, 10, 12 and 14 amperes.

The drop of potential at the *positive* carbon I find is affected both by the length of the arc and the value of the current, and the connection between this P.D. in volts, the current in amperes and the length of the arc in millimeters may be expressed by the equation:

$$V = 31.28 + \frac{9+3.1l}{A}. \qquad (1)$$

The drop of potential between the arc and the *negative* carbon, on the other hand, is, I find, affected by the *current* only, and *not* by the length of the arc. The equation expressing its connection with the current is—

$$V = 7.6 + \frac{13.6}{A}. \qquad (2)$$

Thus this drop of potential at the *negative* carbon is by no means insignificant, nor have I ever found its sign to change, either with silent or with hissing arcs, as it is said to do by some observers. In all my experiments this drop of potential has been from arc to carbon, and its value has been about one-fourth of the value of the corresponding fall of potential at the positive carbon.

From equations (1) and (2) we can find the equation for the drop of potential at the positive carbon plus the drop of potential at the negative carbon; i. e., the whole fall of potential from carbon to carbon minus the fall of potential through the arc itself. It is

$$V = 38.88 + \frac{22.6 + 3.1l}{A}. \qquad (3)$$

Now the equation I found three years ago for the *total* P.D. between the main carbons, which included, of course, the drop of P.D. in the arc itself, was

$$V = 38.88 + 2.07l + \frac{11.66 + 10.54l}{A}. \qquad (4)$$

The coincidence between the first terms of equations (3) and (4) shows that this constant quantity has at last been tracked home, and that it belongs *not* to the positive carbon alone, as has hitherto been supposed, but to *both* the positive and negative carbons in the proportion of about four-fifths to the former and one-fifth to the latter.

It must be remembered that the experiments upon which equation (3) is based were made nearly two years after those from which equation (4) was obtained, and that for the new equation (3) itself the experiments consisted of two entirely separate sets, the one made to find the drop of potential at the positive carbon and the other to find the drop of potential at the negative carbon.

As regards the accuracy with which equations (1), (2) and (3) express the results of the experiments, it may be mentioned that each of the 124 values from which these equations for the fall of potential at the carbons alone were formed was the mean of the results of from 6 to 12 experiments. Of these 124 values 96 differed by less than 1 volt from the numbers calculated from the equations, 25 differed by between 1 and 2 volts, and only 3 differed by more than 2 volts, and these three all belonged to equation (1).

This closeness of agreement between the observed and calculated values is the result of no series of ingenious guesses, but of the algebraical expression of three very simple straight line laws which I find exist between the power expended at each of the carbons, the current flowing and the length of the arc. These three laws may be most simply expressed thus:

If W be the power in watts expended at either of the carbons (measured by multiplying the current by the fall of potential at the carbon) and a, b, c, d, e and f be constants, then for the positive carbon

$W = a + bA$ with a constant length of arc,

$W = c + dl$ with a constant current.

For the negative carbon $W = e + fA$.

A combination of the two first laws gives equation (1) and the third gives equation (2).

The method employed for finding the above falls of potential at each of the carbons was not original. It was first used by Lecher ten years ago, and has since been employed by Uppenborn, by Prof. Silvanus Thompson and by many others. These, however, all used a third carbon placed in a stationary position in the arc, while I considered that more accurate results could be obtained by bringing the point of the third carbon up to touch the hottest part of the main carbon, and observing the last P.D. registered by the voltmeter before it fell to zero. Very accurate and definite results were obtained in this way compared with any I could get by the ordinary method, but in interpreting these results it is necessary to take into account the disadvantages under which all experiments made with a bare carbon dipping into the arc labor.

1. The third carbon may not take up the exact potential of the part of the arc in which it is placed.

2. If it does it will bring all the parts of the arc that it touches to practically one potential, which will be greater than the least and less than the greatest of the potentials that existed in that portion of the arc before it was occupied by the exploring carbon.

3. It repels the arc, and therefore makes its real length greater than its apparent length. Hence the

* Abstract of paper read before the British Association, Section A, Bristol, Eng., Sept. 12, 1898.

insertion of the exploring carbon usually increases the P.D. between the main carbons by from one-half to two volts.

As regards the first disadvantage, it is of course possible that there is a contact P.D. between the carbon vapor and the solid exploring carbon, but, even if it exists, this P.D. is probably small compared with the P.D.'s with which we are dealing, and I have therefore neglected it in the calculation of the equations.

The second point appears to be much more important, for it is quite possible that the variable part of the fall of potential at each of the carbons, given by equations (1) and (2), may be mainly produced by the exploring carbon being in communication with the arc, not only at its tip, but also along a part of its length. For whether the fall of potential at the carbon itself be a constant or not, it is certain that the potentials of the other points at which the arc touched the exploring carbon varied both with the current that was flowing and with the length of the arc, before that carbon was inserted. Hence at least a portion of the variation in the values given by equations (1) and (2) must have been created by the use of a bare carbon in the arc, and it is at least *possible* that the whole of those variations were created in the same way.

Many attempts have been made to explore the arc with insulated conductors, notably by Uppenborn, who tried wires embedded in clay, steatite and glass tubes, and had to abandon them all. I myself have tried asbestos coverings for the carbons, but the asbestos melted and fell in drops like metal. Now that the importance of insulating the exploring carbon is so very apparent, however, it will be worth while making a very great effort to find some insulating material that will stand the heat of the arc, and will yet not have to be so thick as to disturb it unduly. This I hope very shortly to do, and thus to completely solve the question of the constancy of the drop of potential at the carbons of the arc.

THE USE OF ELECTRICITY IN THE SPANISH-AMERICAN WAR.*

BY THOS. G. GRIER.

The application of electricity in the Army and Navy for its various and many purposes is recent, but its progress is rapid. The object of this paper is more to note the uses than to describe the details.

The fortification board established ten years ago by the United States Government has developed complete and elaborate plans for the equipment of coast fortifications.

In these plans electricity plays a very important part. Submarine mines connected by cable with harbor forts have been planted, electric light and power stations have been installed, searchlights, motors, telephones, telegraph instruments and many other devices have been used in preparing for the defence of our harbors.

Range finders for determining distances were extensively used; these instruments may be dependent upon electricity for their operation, as in the case of the Fiske range finder, or may be operated mechanically.

Just prior to our recent war with Spain 200 Lewis depression range finders were ordered by the United States Government to equip our various fortifications. While these instruments are operated mechanically, their efficiency in action depends upon the application of electricity in communicating the distance observed to the gun captain or commander.

To condense as much as possible, a brief summary of the applications can be given by describing the methods employed at Fort Wadsworth, which lies just below New York City. In this fort the fire commander directs the attack from a sheltered station equipped with a Lewis range finder. There is also a position-finder station and four battery commander stations. The fire commander is in direct communication with all by means of telephones.

In the position finder's station, together with numerous other instruments, is a dial telegraph, electric clock and telephone. One of the guns is equipped with a dial telegraph and another with a Sheey teleotype, an instrument which indicates the azimuth or angle from a predetermined line and gives the range or distance in yards the observed vessel is from the fort.

All of the commanders' stations are, however, connected with the guns both by speaking tubes and telephones.

Observations are signaled to the guns, and the course and speed of a ship are plotted upon a miniature representation of the harbor. By means of an electric clock placed at every station absolute uniformity of time is obtained, and the probable course and range of a vessel for several minutes can be plotted from these observations, and without even seeing the vessel the gun can be elevated for the range and trained for the proper angle, and by means of a stop watch the order to fire given so that the shot will fall upon the deck of a vessel whose course has been observed by men at a distance from the guns. The introduction of electricity for signaling has given this wonderful control to the fire commander over his batteries.

Sandy Hook, at the mouth of the harbor, is connected by cable with Fort Wadsworth, and the approach of hostile ships may be telegraphed to the fire commander so that their course may be watched and the fort prepared at the proper time to do justice to the work before them.

Sandy Hook was placed in telephone communication also with Washington during the summer, so that the Government was in position to receive or send messages to the fortifications.

Fort Wadsworth has two 60,000 candle-power searchlights to sweep the harbor and guard against the approach of vessels on dark and stormy nights.

An electric light and power plant forms a portion of the outfit, with a reserve storage battery to supplement the power station.

The channel above the fort is mined, and should some of the vessels of a hostile fleet pass the guns of the fort, the observer at the submarine station would be plotting the course of nearby ships by means of range finders or by information furnished them by the fort and at the proper time fire the mine and sink the remnant of the fleet.

The mining of the harbors was an important part of our coast defenses, and the greatest demand for electrical wires and cables was for "torpedo cables" for use in submarine mines. It seems that our coast defense department has for years requested that an appropriation be made for cable, but the appropriations have been so cut down that not more than 5 per cent. of the amount needed was carried on hand by the Government. There are two styles of cables used, a multiple cable of seven conductors which is used to connect the shore end to a junction box in the channel, and a single conductor cable which connects each conductor in the multiple cable to an independent mine, each conductor being numbered. Any mine may be exploded at will from the shore.

When war was declared each of the manufacturers of submarine cable in this country received orders for all they could make in thirty days, and some were kept busy for sixty days, producing probably two hundred miles of multiple cable and two hundred miles of the single conductor. This has been distributed from the Bay of Fundy to Florida. Some was sent to the Gulf cities and some to California, Oregon and Washington. One hundred and fifty miles of each size was under contract in the early part of August. The cost of seven conductor cable averages about $1,900 per mile, and the single conductor about $450 per mile.

SUBMARINE MINES.

There are three different kinds of mines used in our harbor defense.

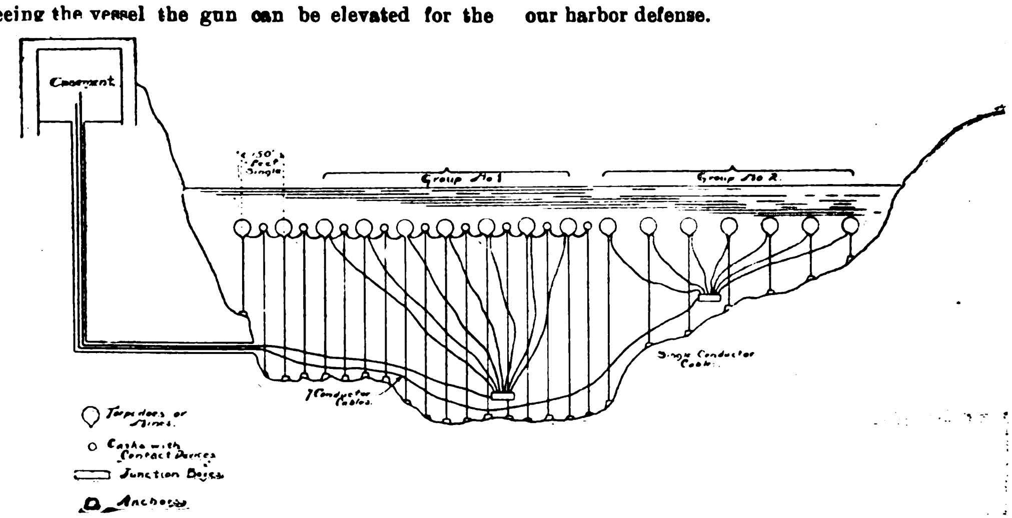

DIAGRAM OF MINES IN BOSTON HARBOR

First—Observation mines, which are fired from shore when a ship is judged by observation to be within effective range of the explosive.

Second—Automatic mines, which are self-firing on being struck by a vessel.

Third—Electrical contact mines, which on being struck by a ship give notice on shore and the operator, by the throw of a switch, fires the mines.

The method of firing observation mines and electrical contact mines are similar. Automatic mines may or may not be fired by electrical means.

Mines may be placed upon the bottom of the harbor, and in such cases are called ground mines, and if they are contact mines the contact mechanism is contained in small buoys anchored at a depth below low-water mark just sufficient for them to be an obstruction in the path of vessels. When the channel is deep, buoyant or floating mines are used. A buoyant mine is more effective, as it lies nearer the object of attack, and for an equal effect does not require as large a charge of explosive.

MINES IN BOSTON HARBOR.

The shape and material of mines or mine cases are various, and the kinds employed at different points not always identical. However, a general description of the mines employed in Boston harbor will give a good idea of the plan and design used in all other harbors.

There were about one thousand mines placed in Boston harbor, covering the main ship channel and ingress to the harbor where vessels of over 12-foot draft could go at low water. The regular Government mine consists of an upright iron cylinder about the shape of a top, with a strap on the bottom for holding the cable. Galvanized steel rope secured by an anchorage of any kind, and in many cases of old horse-car rails, maintained the mines in position.

* Abstract of paper read before Chicago Electrical Association, October 7, 1898.

The cable containing the electric wires runs up separately from the cable holding down the mines.

As the demand was urgent and no mines of the Government pattern were to be had, the engineers in Boston used new ale barrels, a hole being bored in one end for the receipt of the contact mechanism and cable. The barrels were encircled with rope to make a sling to hold them down, a flat steel ring put around the rope so that the steel anchor cable attached to it would not cut through. These mines were of different sizes and held from 100 to 500 pounds of explosive gelatin. Ordinary dynamite was used in some mines where there was not enough gelatin to be obtained. This was put in through a small hole in the top where the electric contact mechanism is placed.

The contact mechanism is connected through high resistance and by a battery circuit, using the cable and ground return for its conductors to an indicating and circuit-closing device located in the protected casement on shore. When a ship strikes a mine containing the device, deflecting the mine from its normal position, the battery circuit is closed; this operates an indicating mechanism which closes a break in the dynamo circuit and notifies the operator. To throw on the current for exploding a mine

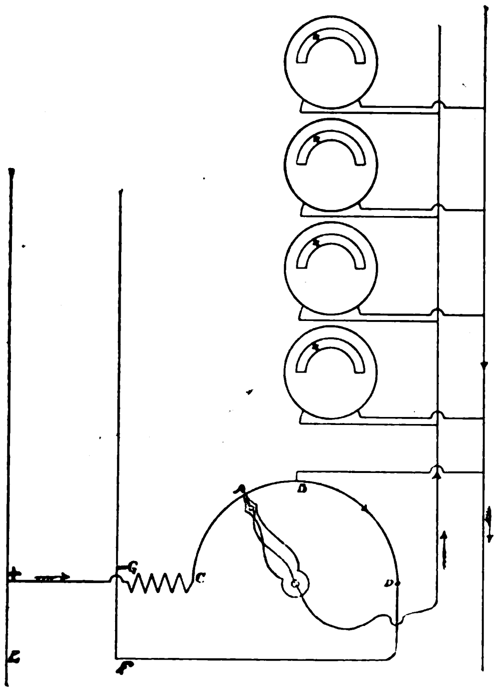

FIG. 1.

it is necessary to throw in a switch or plug after the first break is closed by the indicating device. This circuit can be closed without any contact from the vessel at the will of the officer in the casement.

The firing switchboards at Boston consisted of an ordinary knife switch suitable to take 500 volts, with a spring which holds it out of contact at all times except when kept in position by the operator. These switches, one for every group of mines, were mounted on slate boards and plainly numbered with large letters. A dynamo developing one ampere at 500 volts, driven by an oil engine, furnished the exploding current.

The contact devices were made under the supervision of Dr. Louis Bell, the engineer in charge for the Government. All the parts of the contacting mechanism were of platinum or gold-plated brass to prevent any possibility of corrosion. The exploder consisted of a thin strip of platinum wire which was laid in a case of fulminate, which in turn was put in a case of dry guncotton; the remainder of the explosive was wet.

The mines were usually placed in groups of seven each, about 150 feet apart. These groups of mines in Boston harbor, as shown in the diagram, were strung clear across the channel, and in the main channel there were three lines.

In this method, should a vessel be sunk by the first line of mines and the wreck not obstruct the passage for other vessels, the second line of mines would catch the next vessel and the third line the third vessel. Between the mines were small casks with contacting devices connected to mines on either side. These were cheaper than mines but were equally serviceable and made the line complete, so that no vessel could get through.

The submarine cables connecting the world's cen-

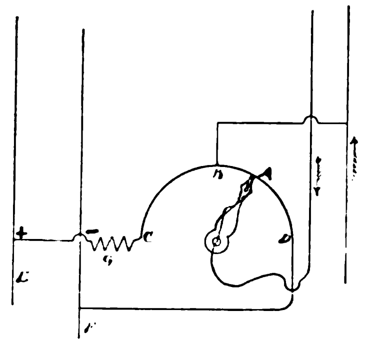

FIG. 2.

ters of humanity—a great system of electric nerves—had a most important influence in every feature of this war. Ships at distant points were enabled to advise and receive information, and movements of fleets could be directed from the seats of government. It is hard to conceive of this almost complete annihilation of time and space.

The Oregon, that speedy and modern man-of-war, equipped with powerful machinery, took eighty-one days to make the remarkable voyage from Puget Sound to Key West, a distance of about 18,000 statute miles, and of this time she was about fifty-nine days at sea. The distance by cable and telegraph from Chicago to Hong Kong is nearly as great, yet to send a message between these two points, including all the delays caused in the many transfers, requires less time in minutes than it took the Oregon days to make the trip.

Our army in the field has its cable tents completely equipped with telephones and telegraph instruments. The telephone at Santiago and adjacent points before and after the siege was of great service, and cable tents now have their names lengthened into the title of cable and telephone tents.

A special cable was furnished the Government, which is used in the signal service by General Greely. It is very light and very strong, weighs about sixty pounds to the mile, and is furnished on reels in half-mile lengths—a two-conductor concentric cable. This outpost cable, as it is called, is carried by a scout on a reel fastened to his back like a knapsack. He carries a telephone, and one end of the cable being connected at headquarters enables him to communicate in whispers to his commander. An attendant accompanies the scout with extra reels, which are easily attached when the wire on the first reel has reached its limit. Telephones, in fact, are used everywhere—in forts, in camps, in the field, and on board vessels.

Among the most recent applications of electricity that found a place in the army and navy was the "X-ray" apparatus. It was used in the field, in the hospitals and on the hospital ships.

Notices were published in the papers of electric cooking outfits, which were going to be placed upon some of the hospital ships, and if it were done there is no doubt that much comfort and convenience resulted, especially when the vessels were in the warm climate of the West Indies.

Aboard modern men-of-war the electric light is found to be absolutely necessary for the efficiency of the ship. Searchlights are used to observe the movements of other vessels, to find buoys or landmarks on entering shallow channels, to pick up disabled boats or men overboard, to make landings and for signaling. The incandescent lamps illuminate the entire ship, dispensing with oil lamps and candles; they are also used for night signaling.

Electric motors are used in hoisting boats and ammunition, for removing ashes, for steering, for training gun turrets and many other purposes.

Steam whistles are opened and closed by electrically operated valves.

The range for guns and the speed and direction of revolving shafts are determined by the electric current, and guns are fired by an electric spark.

Telephones and electric signaling devices aboard ship are extensively used.

This in brief covers the application of electricity ashore and afloat in the recent Spanish-American war.

A description of the principles governing some of the signaling devices on board ship will materially assist in showing to what a great extent modern vessels depend upon electricity.

The signaling and indicating devices used on vessels are: "helm indicators," "steering telegraphers," "speed indicator," "direction indicator," "range indicating system," "Fiske range finder," "azimuth telegraph" and "transmitter of orders." All of the devices consist of galvanometers, which indicate on their dials a difference of pressure, the dials being marked for the different offices the instruments perform, and with each instrument or system of instruments proper devices are used for

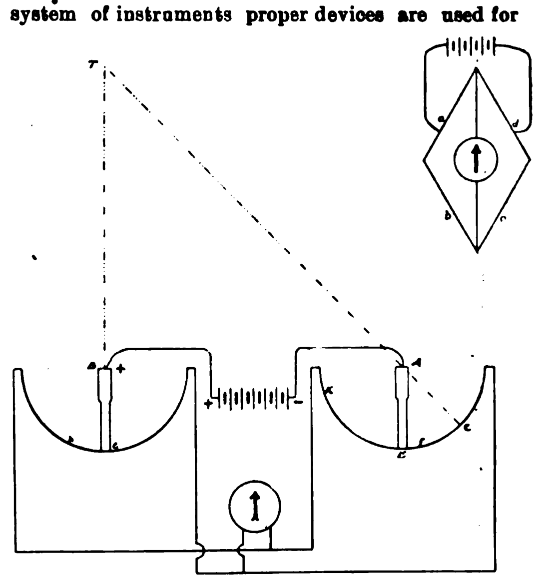

FIG. 3.

altering resistances and consequently changing pressures to accomplish ends in view. A description of the principle applied to the helm indicator will explain the operation in general of all the others.

The object of the helm indicator is to indicate at different parts of the ship the position of the helm. The principle of operation is shown in Fig. 1. Attached to the helm and insulated from it is a metallic contact, A, which presses continually on an arc of resistance wire, C D. At the center of this resistance wire is a permanent contact, B, which is connected by a wire to one side of a number of galvanometers located at various stations. E and F are the negative and positive wires of the electric lighting system. Primary or storage batteries also could be used as the source of energy. A dead resistance is inserted in the circuit connected with the arc of resistance wire, C D, which reduces the current to about two amperes.

The current flows as indicated by the arrows. As the pointer, A, is moved toward the left, or toward C, the difference of pressure A and B becomes greater and the flow of current through the galvanometer is greater. The galvanometers are adjusted so that they take the same angle as the helm, or pointer A. In Fig. 1, when the pointer is on the left of B, its pressure, as compared with B, is positive. When B and A are both in the center, or when the pointer A coincides with the fixed point of contact B, then the needles of the galvanometers come to rest at zero or the center of the scale. When A is moved toward the right or toward D, then the conditions are re-

versed (Fig. 2), A becomes negative compared with B, and the current flows in the opposite direction in the galvanometer, bringing the needle toward the right. One of the instruments can be on the bridge, one in the captain's cabin, one in the wheel house and one in the conning tower.

The steering telegraph is the same arrangement of galvanometers, with a device for altering the resistance by hand. The captain sets the resistance from his station, having an instrument before him. The same indication appears upon an instrument in the wheelhouse, and by noting the helm indicator the captain is advised when his order is obeyed. The same thing is true of the engine telegraph, the transmitter for orders and the azimuth telegraph.

In the Fiske range finder the general principle is the measurement of the resistance of a conductor in the form of a Wheatstone bridge, there being two arcs of wire at the ends of a base line, corresponding to two contiguous members of the bridge. Two telescopes are located at the ends of the base line and carry contacts which move over the resistance wire as the telescopes are turned to be pointed upon any object.

In Fig. 3, let the arms *a*, *b*, of a Wheatstone bridge be represented by arc *h* while *c* and *d* are bent into arc *k*, both of these arcs being wires of conducting material. Let contacts *e* and *s* be attached to telescopes pivoted at A and B. When the telescopes are parallel and when at right angles to the base line, the galvanometer will not deflect and its point of rest is marked infinity. Now let the telescopes converge and the angle of convergence is A T B, and presuming the telescope at B is pointing at right angles to the base line, the angle of convergence is measured by the arc C E. The bridge is out of balance, that is, the needle deflects, and the amount which it is out of balance will vary with the difference of position of the telescopes. The angles of convergence are not indicated upon the galvanometer, or reading instrument, but the deflection of the needle is marked in yards.

The speed indicator is, in reality, a small alternating-current dynamo, the current being great or small according to the speed of the shaft, and the strength of the current indicating upon an alternating-current galvanometer graduated in revolutions per minute. Six soft iron cores or inductors fastened to an iron ring on the shaft form the armature. These are rotated, the pole of a north and south magnet having two coils of wire at its extremities, the coils of wire being connected in series with the galvanometer.

The direction indicator simply tells in which direction the shaft is turning. A permanent magnet fastened to a ring on the shaft revolves in front of a soft iron bar, around which is a coil of wire that is connected to a galvanometer. The shaft revolving in one direction throws the pointer to one side, and when its direction is reversed throws it to the other side.

Enamels.

The use of enamel as the insulator for the resistance wires of electric heating and cooking apparatus is now general, and manufacturers have found out which enamels give the best results. The desiderata are, firstly, that the expansion of the enamels shall be about the same as that of the metals employed, and secondly, that the enamel shall not be very brittle. Mr. Saglio's researches on highly-expansive enamels, contained in his paper to the Société d'Encouragement de l'Industrie Nationale, are of interest in this respect. He found that silica, kaolin, petalite and zircon impart to the enamel infusibility and insolubility, but lessen the expansiveness; that calcic phosphate increases the expansiveness, gives viscosity to the enamel in fusion, and imparts to it a certain insolubility; that cryolite, fluorspar, and above all, rutile (which seems to fix the boracic acid well), increase the expansiveness and the fluidity of the enamel.

ELECTRICAL DISTRIBUTION ON BOARD SHIP.*

BY J. C. BAGOT.

The underlying principles requiring consideration in fitting up vessels with electric light are, generally speaking, outside the experience of the average electrician engaged on land; in fact, the requirements are unique in this department of electric lighting. The methods adopted for distribution on land are generally applicable on board ship, but the system that is chosen, "where practicable," in the majority of cases is the single wire system, in which case the negative pole of the dynamo is placed in contact with the iron of the vessel, which serves for the return circuit. The precautions to be taken are set down in Lloyd's rules affecting electric light on board vessels, but the arrangement of the circuits will depend to a great extent upon the design of the vessel and the places to which the current is required to be carried. The conductors are in almost every case divided into mains, sub-mains and branches. The dynamo should be situated as nearly in the center of the vessel as possible, so that the lights and mains may be divided into two sections, one running forward and the other astern. If the installation be a large one and two dynamos are employed, these two sections may be independently supplied, for by this arrangement an accident in one machine will not affect the working of the other; also reducing the length of the runs of the leads and the loss due to fall of potential, and consequently a reduction in the cross-section of the conductors employed. This is also true if one machine only be employed, providing the divisions are equally balanced beween the two sections. The forward and the astern mains can also be divided into two portions, one running on the port side and the other on the starboard side of the vessel; then the ends of these two branches are joined further on, forming a loop circuit. The following lights are generally what are required on board ship:

1. *Ordinary Lights.*—These lights are placed in such positions where there is plenty of light during the day, such as the cabins, which have large portholes; and the time during which these circuits are in use is usually from 6 P.M. to 11 P.M., at which hour they are switched off from the main switchboard, so that no lights which are liable to be required at irregular hours should be connected to this circuit. The ordinary lights are distributed over four decks generally—namely, the promenade deck, the upper deck, the main deck and the lower deck—with a separately controlled circuit from the dynamo-room.

2. *All-Day Lights.*—These will probably be required on each deck, so that each circuit must be separately controlled. The time during which these lights are required is from 6 A.M. to 11 P.M.

3. *Detective Lights.*—These are used for giving a very feeble light when all other lights are extinguished in the passenger part of the vessel; consequently they must be placed so as to show a continuous light through the length of each deck. These have a circuit of their own.

4. *Cargo Lights.*—The arrangement of these lights will depend upon the position of the hatchway to the holds and the shoots to the coal bunkers. The branches from the mains in these cases will run to terminals instead of lamps, for flexible connections are used in such places, in order to allow the lamps to be lowered in the hole when taking cargo.

5. *Gangway and Passage Lights.*—These are used on the outside of the bulkheads of deckhouses, and are arranged as nearly as possible at equal distances.

6. *Masthead and Side Lights.*—The main circuit for these lights will run to the forward portion of the vessel, only they must in no case be connected with any other circuit, and it should pass through the wheel-house or steering-house, where the switch should also be placed. These lights are fitted with a positive and negative lead complete, irrespective of the system adopted.

7. *Engine-Room and Boiler Space.*—The main circuits for these spaces are nearly always distinct from each other, and the branches are taken from them by means of specially constructed distributing boxes to meet the requirements of the case.

8. *Searchlights.*—The circuits for these on board ship are special; they are directly controlled from the main switchboard, and should always have a positive and negative lead.

The mains are run along the under side of the upper deck, which, of course, is the top of the main deck. The first advantage gained by selecting this position is that the cables are under a watertight cover, and by placing the casing which carries them with grooves downwards no water can lodge in them. Secondly, all the connections of the sub-mains and branches can be made on one deck, which also enables the fuses and switches to be placed near to the joints, with the advantage of being able to control every deck and group of lights from one deck, and there will be less difficulty in tracing any set of wires from its fittings in the event of breakdown.

Before proceeding to put up any casing, the holes through the beams and other ironwork which cross the boat should be drilled. These holes must be large enough to take easily all small cables it is found necessary to carry through, after the holes have been well insulated by a vulcanite or papier maché ring. When the leads are run through watertight iron bulkheads, a special piece of apparatus is necessary where several cables are to be carried through. This consists of a cast-iron trough with holes in the side just large enough for the cable to pass through; then the trough is filled with some insulating compound. But for small cables, and where there is no great number, another method is adopted. After the cable is placed in the proper position, one end of this tube is stopped, and melted insulating compound is poured into the open end. This is done and the compound allowed to set before the tube is placed in the hole.

In respect to the casing, several methods have been tried to render the casing impervious to moisture by the application of insulating substances which will fill up the pores of the wood. The most practical substance has been found to be a wax with a high melting point. The method of applying the wax is to melt it in an iron trough long enough to take the greatest length of casing, which will rarely require to be more than 10 ft. for shipwork. Where the mains or sub-mains have to pass from one deck to another, whether of iron or wood, wrought-iron tubes are employed. These must be galvanized, and stand 6 in. above the deck. When these tubes are fixed, the surplus thread at the bottom is cut away, and the casing is so fitted as to completely cover the nut.

The chief cause of failure to be guarded against is the action of the salt water, which in the form of vapor soon finds its way into every part of the vessel, and causes the greatest damage to the fittings by lodging in places which cannot easily be got at, forming rust on ironwork and rendering woodwork a good conductor, which increases the risks due to leakage, and the insulation resistance is soon found to be below the standard. The water will soon penetrate through the joints in the deck, which, if it has not also an iron deck beneath, will expand and contract by the influence of the water and the sun. This is always the case in a new vessel, and the fact should be remembered in choosing the positions for switches, fuses and other fittings; also the strain to which every part of the vessel is subject when rolling, which opens crevices in bulkheads, straining casings and fittings, and loosening nuts and screws.

In the methods above considered it is assumed ordinary insulated cable is employed, for there are

* From the *Electrical Engineer*, London.

other precautions to be taken, which principally arise from the nature of the cable employed and under what conditions. These conditions will be different in almost every ship. But the most important consideration is the variation of climate through which the vessel passes, so that when selecting the most suitable cable all the above items respecting the insulating material must be considered. When the installation is finished, "and if the separate circuits have been carefully tested during the progress of the work," there will be very little to fear when the current is finally switched on. But, in addition, a final test should be made for insulation resistance. The directions for making such tests are always given with the instruments, but the voltage used in testing must be above the working pressure.

In the above notes the general details and minor considerations affecting all installations are assumed to be well known.

THE JACQUES CARBON BATTERY.

Mr. John W. Langley contributes to the *Journal* of the Franklin Institute for September, 1898, an interesting paper on the above subject, founded on the works of Messrs. H. S. Rosewater and W. H. Oldham, two students in the Case School of Applied Science, Cleveland, O. It will be remembered that Dr. W. H. Jacques, of Boston, recently patented a cell in which electrical energy is obtained directly from the consumption of coal, the efficiency of the process being equal to 32 per cent. instead of the ordinary value of 6 or 8 per cent. In the arrangement used by Dr. Jacques a rod of compressed coal dust, which forms one electrode of the battery, is supported in a vessel containing fused caustic alkali, through which oxygen is blown. The electric energy obtained is ascribed by Dr. Jacques to oxidation of the coal, just as zinc is oxidized in a Daniell cell. On the other hand, Mr. Reed considers the effect to be a purely thermo-electric one. Considering that we might distinguish between these two theories by forcing nitrogen through the cell, it is difficult to see why the subject has not been brought to a definite issue. Reed has passed coal gas through the fused alkali, and found the resulting EMF. equal to that when oxygen was used. Messrs. Rosewater and Oldham used an iron cell, which virtually formed one terminal of the battery, the other terminal being composed in turn of copper, iron and carbon. The pot was then filled with caustic alkali, which was kept fused, whilst a current of air was blown through it.

Curves were obtained showing the relation between the temperature of the pot, the EMF. produced, the amount of air admitted, the nature of the electrode, etc. Mr. Langley concludes that there can be no doubt that the current produced is of thermo-electric origin. In the first place, the general appearance of the curve plotted is characteristic of a thermo electric curve, showing sudden changes in magnitude and direction. Then the maximum voltage occurs when the difference of temperature is greatest. Further, blowing air containing oxygen through the pot ought to increase the potential between the electrodes; this was found not to be the case. The addition of sodium nitrate to the fused alkali was found to reduce the P.D. between the electrodes. The EMF. found by Messrs. Rosewater and Oldham was much smaller than that given by Dr. Jacques. They ascribe this to the smaller size of their pot, together with the very gradual and even heat employed, which tended to lessen the difference of temperature between the electrodes. The subject is, however, by no means settled as yet. There can be little doubt that the passage of an electric current through fused caustic alkali is accompanied by electrolytic decomposition, and it is difficult to imagine the generation of a sufficient pressure by thermo-electric means to effect this decomposition. Anyway, electrolysis must be taken into account, and any theory which neglects this side of the question can hardly hope for ultimate acceptance.—*Elec. Engineer, London.*

CANADIAN NOTES.

The city engineer of Toronto, Ont., has refused to draw up specifications for a 6,000 horse-power municipal power plant as ordered by the city council, and has recommended that $1,000 be appropriated to secure the services of an expert consulting electrical engineer who would draw the specifications.

A United States company which is going to develop the water power of the Jacques Cartier river, in the Province of Quebec, for electric light and power purposes for Quebec City in opposition to the Montmorency Company, has now acquired the chartered rights, as regards the city of Quebec, of the Standard Light & Power Company of Montreal. The American company has a capital of $500,000, and its president is Emerson McMillin of New York.

The Niagara Central Railway has been bought by Haines Bros. of New York. The road will be converted into an electric road, and it is said there will be a 40 minute service between St. Catherines and Niagara Falls. The trestle work at Merritton, Ont., and Thorold will be done away with, and the road run on the ground, the motor cars being able to overcome grades which steam cars could not do. The plans also include the extension of the road.

Although it is only a few years since the first electric railway was built in Canada, it is now possible to obtain in the Dominion all the materials necessary for the complete equipment of an electric road. In the case of the street railway recently completed at St. Thomas, Ont., with the exception of the overhead joists and fixtures, the line was built and equipped with Canadian material, the total cost being $85,000. The rails were made at Hamilton, Ont.; the engines at Amherst, N. S.; dynamos and electrical equipment at Peterboro', Ont., and the cars at Ottawa.

The Engineer Corps in the War.

Brig.-Gen. John M. Wilson, Chief of Engineers, U. S. A., has submitted to Chairman Dodge of the War Investigation Commission his reply to the questions asked by the commission regarding the operations of the Engineer Corps during the war with Spain. Gen. Wilson gives an outline of the work on coast fortifications during the war, the expenditures for which aggregated $4,821,500. Submarine mines to the number of 1,535 were planted in twenty-eight different harbors, together with all their cable, anchors, junction boxes and electrical apparatus. A large number of additional mines with all accessory material were held in readiness to replace mines lost by accident or design, and to extend the mined areas if necessary. In this work were required a large corps of skilled electricians, instrument men, sailors and laborers, in addition to small detachments of engineer troops sent to each locality, with a fleet of tugs, lighters and rowboats for planting the mines, repairing damages and patrolling the mined areas. The expenditures on account of torpedoes for harbor defence to August 1, 1898, amounted to about $1,661,000.

A National Electrical Trades Association.

A national organization of the various electrical trades associations throughout the country was perfected in Cincinnati on the 7th inst. The officers elected are: President, R. E. Gallahar of New York; vice-president, C. M. Wilkins of Philadelphia; secretary and treasurer, Fred P. Vose of Chicago. The board of managers consists of the three officers just named, together with L. R. Keck of Cincinnati, James Wolf of Chicago and W. S. Barker of Boston.

Pennsylvania Street Railway Association.

The seventh annual convention of the Pennsylvania Street Railway Association will be held in Scranton on October 19 and 20.

LEGAL NOTES.

An assignment was made in the County Court at Chicago on the 8th inst. by the Orne Electrical Construction Company, E. Wallace Pease being named as assignee. The assets of the company, consisting of its stock and machinery, are estimated at $5,000. It is thought the liabilities will not exceed the assets. W. N. Wegg is president of the assigning corporation.

The jury returned a verdict for the defense in the suit brought by the La Crosse Department Store Company against the Edison Light & Power Company of La Crosse, Wis. This is the famous "White House" case. The action was brought to recover $60,000 damages. The large store and practically the entire stock of goods were destroyed by fire in December, 1895, and plaintiff claimed that the fire was due to the defective wiring of the defendant company. A year ago the case was tried and the result was a disagreement of the jury. The plaintiff, it is said, will appeal to the Supreme Court on grounds of improper admission of evidence and the judge's charge.

The Denver *News* of the 7th inst. says: "An action to foreclose upon the property of the Colfax Electric Railway Company was commenced in the District Court yesterday morning by George E. Ross-Lewin, trustee for the bondholders. The bill states that $150,000 worth of first mortgage bonds were issued by the road in 1891, and that all the property was conveyed in trust to Joseph H. Thatcher. The latter afterward assigned all his rights in the trust to the plaintiff, Ross-Lewin. It is stated that in December, 1891, the company made default in the payment of its interest and that no payments have been made since then. Ross-Lewin says that he has been instructed by a majority of the bondholders to institute proceedings in foreclosure. The corporation is said to be wholly insolvent, and the financial affairs are in an embarrassed condition."

John G. Gray, 15 years old, obtained a verdict for $10,000 damages for the loss of his left leg against the Metropolitan Street Railway, New York, before Justice Truax of the Supreme Court on the 11th inst. Gray took a Lexington avenue car on January 5 last and rode to Fifty-ninth street, where on a transfer ticket he boarded a crosstown car. He says the latter car was so crowded that he had to get on the front platform, and that when the conductor pushed through to collect the fares he was pushed off and received injuries that necessitated the amputation of his leg.

In the case of Edward Thayer against the Scranton Traction Company, tried at Scranton, Pa., last week, Judge W. W. Porter of the Supreme Court filed an opinion against the plaintiff on the ground of contributory negligence. Thayer was a passenger on one of the defendant's cars, and stood on the back platform when there were vacant seats inside. A collision occurred and the plaintiff was thrown backward, striking the dashboard with his back and falling into the street. He sustained injuries to his back and internally. After discussing the differences between steam cars and street cars, and quoting several decisions covering both, Judge Porter says the trolley car is quite unlike the horse car, and that transportation upon an electric car is quite as perilous as upon steam roads. Continuing, he says: "We reach the conclusion, then, that the platform of an electric car is a place of known danger, and if, while there, a passenger who could have found a seat within is injured, he is guilty of contributory negligence, provided his presence on the platform contributed to the injury he received." It is held that such was the case in this instance, for if the plaintiff had been inside he would not have been injured in the same manner or to the same extent, and possibly not at all. The opinion says it was the duty of the judge below to direct the jury to find for the defendant. Judge Smith filed a dissenting opinion, in which Judge Orlady concurred. Judge Smith holds that the platform of electric cars is not recognized by the public in general as a place of peculiar danger, and that long experience has shown this view to be correct.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING.

Akron, N. Y.—The taxpayers of this village have ratified by a vote of 40 to 8 the proposition to purchase a $3,000 electric light plant for the village.

Atlanta, Ga.—At the election held here on the 6th inst. there was a decisive majority in favor of municipal ownership of the local electric lighting plant. As a consequence the city will immediately take steps, by condemnation proceedings, unless a fair purchase price can be agreed upon with the private owners, to take possession of the plant.

Canandaigua, N. Y.—M. D. Munger, of this town, has asked the board of trustees for a franchise to establish an electric light plant in Canandaigua. Mr. Munger was formerly president of the local street railway.

Elk Rapids, Mich.—A company to be known as the Elk Rapids Electric Light Company will probably be organized shortly, as steps are being taken in that direction by leading business men. There is a strong demand for electric lights.

Florence, Ala.—F. M. Perry, a large landholder and capitalist, is erecting a flouring mill and cotton gin on Cypress Creek, just outside of the city, and proposes to erect an electric light plant to be run by the same water power if he secures a contract for street lighting from the city.

Fredericksburg, Va.—The committee on light of the council has made arrangements to get power to operate the new electric light plant to be built by the city from the water power in this vicinity owned by Mrs. Martha E. Clarke.

Grand Rapids, Mich.—The electric lighting contract awarded by the council to the Chase Construction Company of Detroit is held up in the council, as it failed when presented for final action to get the requisite vote.

Hallstead, Pa.—A contract for lighting the village has been made with a private company by the borough council, and the electric plant will be erected at once. The Delaware, Lackawanna & Western Railroad Company will place 14 arc lights in their yard here, and several citizens have agreed to take the light for their houses and business places.

Horton, Kan.—An electric company of Cleveland, O., has been granted the right to construct and maintain an electric light plant in this city.

Marshfield, Wis.—The bid of the Marshfield Water, Electric Light & Power Company for lighting the city was rejected by the council as being too high, and the mayor has appointed a committee to investigate and ascertain the probable cost of maintaining and operating a plant to be owned by the city.

Marcus Hook, Pa.—Walter G. Rust has been granted a franchise for an electric light plant in this borough, with these conditions: that the poles and wires he erects do not interfere with other wires and poles in the borough; that the poles are straight and neatly painted; that at any time Mr. Rust stops running the plant the wires and poles are to be removed; that the borough shall have the use of the poles for a fire alarm system, and lastly providing that Mr. Rust gives security for a strict compliance with the ordinance. The poles and wires are to be exempt from taxes for the period of five years.

Minneapolis, Minn.—City Engineer Cappelen has been instructed by the city council to attend the National Convention of the American Society of Municipal Improvements to be held in Washington, D. C., on the 26th, 27th and 28th inst. Mr. Cappelen as the chairman of the committee on electric street lighting will submit to the society an exhaustive report on that subject which he has just completed. The report, which must have entailed lengthy and painstaking research, contains a mass of statistics showing the cost of electric street lighting in every city of any importance throughout the United States. The expenses are shown in detail, including the cost of steam plants and electric plants and their operation, machinery, miscellaneous tools, conduits, towers, lamp posts, arc lamps, clerical hire, etc.

Montevideo, Minn.—The Montevideo Roller Mills & Electric Light Company sold its mill and electric light franchise with all the appurtenances to the James Quirk Milling Company of Waterville, Minn. The electric light plant cost over $10,000 two years ago.

Monroe, La.—An election is to be held here on November 9 to vote on the question of issuing bonds for waterworks, an electric light plant and other improvements.

Mullica Hill, N. J.—A movement is assuming shape for having the town lighted by electricity.

New Orleans.—The Crescent City Electric Light Company, a new electrical concern which will soon start business here with a capital of $750,000, has secured an admirable site for its power house.

New Whatcom, Wash.—A new electric lighting plant is to be erected here to take the place of the plant destroyed by fire. Improvements costing $65,000 are to be made, the result of which will be to furnish New Whatcom with an equipment sufficient to supply the entire city with domestic and street lighting equal to any municipal corporation in the West. G. R. Loughden, an electrician, formerly of Pittsburg, Pa., has been placed in charge of the plant and will push it to an early completion.

Orangeburg, S. C.—Commissioners of Public Works J. G. Wannamaker, T. C. Doyle and T. M. Raysor are figuring on the cost of water works and an electric light plant for the city, and will have to bring it within the limit of $40,000, the amount of bonds voted for the purpose.

Rutherford, N. J.—The sale of the lighting plant of the Rutherford, Boiling Springs & Carlstadt Electric Company, which was to have taken place on the 5th inst., was postponed at the request of counsel until November 5. The sale was ordered to satisfy a mortgage of $35,000 held by the Franklin Trust Company.

Saratoga Springs, N. Y.—Albert L. Judson of Albany has applied to the board of street commissioners for a franchise for an electric light and gas plant to be established in this city.

South Milwaukee, Wis.—The mayor has vetoed the resolution passed by the council for the purchase of the electric light plant from the company now serving the city with light.

The Dalles, Ore.—The council has decided to enter into a contract with the electric light company to provide 15 arc lights for the city streets at $10.50 each per month.

West Union, O.—A. A. Kirchner & Co. of Manchester, O., have made a proposition to the town council to put in an electric light plant here and guarantee to furnish light cheaper than the gasoline lights now in use if the council will grant them a 20-year franchise.

Winona, Minn.—The council has appointed a committee to investigate the feasibility of the city operating its own lighting plant.

STREET RAILWAYS.

Abington, Mass.—The controlling interest in the Rockland & Abington Street Railway Company has been purchased by Pepper & Register, a Philadelphia firm. The road was built in 1892, and the capital is $120,000. It has been a success from the start, and has always paid an annual dividend of 6 per cent. Its first president was the late Maj. E. P. Reed, and since his death Moses W. Arnold of North Abington has been the president. The road runs from Whitman through Abington to Rockland and South Weymouth.

Atlantic City, N. J.—The Atlantic City Street Railway Company, of which Congressman Gardner is one of the promoters, has been granted a franchise to maintain a crosstown railroad in this city.

Austin, Tex.—The council has passed an ordinance granting E. A. Ellis and associates the right to build and operate a street railway in this city.

Burlington, Vt.—It is expected that the Burlington & Hinesburgh electric road, on which work is about to begin, will be completed before the 1st of July next year. The grading will be finished this fall.

Fort Smith, Ark.—A new company is to be formed here to take over the street car line and transform it into an electric system to be operated in conjunction with the electric light plant.

Frederick, Md.—The Catoctin & Myersville Electric Road, which has been building for several months, is now nearly completed. The road is five and one-half miles long and connects the Frederick & Middletown road at Middletown with Myersville. The Frederick & Middletown Company will furnish the rolling stock and operate the new road.

Hampton, N. H.—The Hampton & Amesbury Street Railroad Company have petitioned the railroad commissioners for authority to issue capital stock to the amount of $40,000 for the purpose of enabling them to construct and equip a street railway in the towns of Hampton Falls and Seabrook, location having been granted by the selectmen of both places. The capital stock of the company is fixed at $75,000.

Honesdale, Pa.—The town council is considering the proposition of a company to establish an electric street railway here. The company offers to build an opera house if they get a franchise for the railway.

Lockport, N. Y.—The Buffalo & Lockport Railway Company has equipped one of the local cars with electric heating appliances, and if these prove satisfactory will similarly equip all their cars.

Logansport, Ind.—The Business Men's Association of this city have been granted right of way through Carroll county for the proposed Logansport & Burlington Electric Railway. Some time ago this association secured the franchise for an electric road from Logansport to Rochester in Fulton county, and later a franchise was granted from Rochester to Winona, in Kosciusko county, with a branch to Manitou lake. Thus the right of way for a continuous line from Burlington, in Carroll county, through Logansport to Winona, about sixty miles, has been secured. The organization of a company for the construction of the road will be undertaken at once, local capital along the line being largely interested.

Lyons, N. Y.—The construction of an electric railroad between Marion and Palmyra is again being talked of. Charles Tassell of Marion is securing the right of way for the proposed road, and it is claimed that part of the necessary capital has been subscribed. It will cost about $70,000 to construct the line.

Media, Pa.—A deed has been filed at the recorder's office here conveying all the property and franchises of the Philadelphia, Castle Rock & West Chester Railway Company to the Philadelphia & West Chester Traction Company.

New York.—President Vreeland states that owing to unexpected difficulties encountered in laying the conduits, the Sixth and Eighth avenue lines, whose motive power is being changed to underground electric, will not be completed before December 1. He thinks the Broadway line will not be finished before spring.—The railroad committee of the municipal assembly has under consideration a proposed ordinance providing for illuminated signs at night on all street cars indicating their destination; for bringing cars to a standstill while passengers get off and on; for refunding fares to passengers in case of obstruction by fires or other obstacles lasting over five minutes; for low steps; for proper lighting of cars to enable passengers to read with ease, etc., etc., and empowering the mayor to appoint inspectors at suitable salaries to see that the provisions of the ordinance are obeyed.—The report of the railroad committee advising that trolley cars on the Brooklyn bridge be required to keep 102 feet apart under a penalty of $25 for each offence was unanimously adopted by the council.

Nyack, N. Y.—The Nyack Traction Company has prepared plans and specifications for the new car barn and power house to be built. Drawings are being made and bids will be asked for in a short time.

Ottawa, Ill.—H. L. Bishop, master in chancery of the United States District Court, on the 7th inst. sold the defunct Streator street railway here for $14,000 to C. S. Barr of Streator, the principal bondholder.

Richmond, Va.—The projected trolley road from Richmond to tidewater at Gloucester Point or that vicinity has aroused so much interest in this city and along the line that a company has been organized to take the enterprise in hand. The incorporators are G. E. Detwiler and a Mr. Enright, of Amelia County, Va.; G. E. Picot, of Richmond; L. C. Catlett, of Gloucester, and Messrs. Taylor and Hunton, of New York. An election will be held at Gloucester on the 8th of November to get the public vote on the question of issuing bonds to aid in carrying out the scheme.

San Antonio, Texas.—An electric freight railway about two miles long is now in operation in this city. The line is owned and operated by the Texas Transportation Company. It extends from the yards of the Southern Pacific Railroad through the streets of the city to a station at the City Brewery, and has a number of spurs reaching the warehouses and storage rooms of the brewery.

San Luis Potosi, Mexico.—A company has been formed for the purpose of building a narrow gauge electric railroad from this city to the mining district of Rio Verde, 66 miles southeast of here. The name of the company is the Potosi & Rio Verde Railway Company. It has a capital stock of $200,000. The directors are George F. Peabody, Edward M. Shepard, A. Foster Higgins, Chas. J. Nourse, Jr., Herbert H. Dean, Samuel H. Ordway and Francis N. Holbrook, all of New York City, and Donald C. Brown and Robert S. Towne of St. Louis. A concession for the proposed road has been obtained from the Mexican Government, and the work of construction will commence in a short time. The road will be used to handle ore from the Rio Verde mining camp to the smelter in this city.

South Peoria, Ill.—The formal opening of the street car line here on the 6th inst. was celebrated in great style. Bunting was liberally displayed, a band played patriotic airs and there was general jollification.

Springfield, O.—An electric railway from this city to Dayton is projected.—The capital stock of the Dayton, Springfield & Urbana Railway Company is to be increased to $1,000,000.

MANUFACTURING, ETC.

Chester, Pa.—The Morris Arc Light Company has received its charter from Harrisburg, and will now proceed with the manufacture of its lamps.

Utica, N. Y.—The Utica Electric Manufacturing & Supply Company has closed a contract for a dynamo, switchboard and 11 arc and 200 incandescent lamps for the New York Mills Company. The plant will be installed at once.

Washington, D. C.—By direction of the Paymaster General of the Navy the opening of proposals for furnishing the Norfolk, Va., Navy Yard with one electric traveling crane has been postponed from October 18 to October 29, 1898. Contractors desiring to bid on this work can obtain full information by addressing the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.

TRANSMISSION PLANTS.

Quebec, Can.—The Shawinigan Water & Power Company have let the contract for the construction of a canal, power house, etc., at Shawinigan Falls on the St. Maurice River, Que., to a firm composed of James Barry, John Ross and John A. McRae of Niagara Falls. The contract calls for a development of 30,000 horsepower, the largest development as yet in Canada. The company proposes to develop power in the form of elec-

tricity and convey it to the city of Three Rivers, 19 miles distant, and other surrounding points. An electric tramway from the falls to Three Rivers is part of the scheme, and the promoters are convinced that electric power can also be transmitted to Montreal, a distance of about 80 miles. The contract awarded to Barry, Ross & McRae represents between $300,000 and $400,000, but the whole expenditure will amount to at least $1,000,000.

COMPANY MATTERS.

Ottawa, Ont.—The Metropolitan Electric Company has been granted a charter by the city council and will apply to Parliament for incorporation as a company. The directors are: James Robinson and F. Caines, Montreal, A. B. Broderick, T. Lindsay and W. Arnold of Ottawa.

Peoria, Ill.—The Diamond Electric Company's works here were sold on the 11th inst. to George C. Bailey of Chicago, representing the John A. Roebling's Sons Company, under whose claim the factory was recently closed. Mr. Bailey's bid was $7,500 and the claim was $10,000. The difficulties of the Diamond company are attributed to a disagreement among the stockholders, and probably after reorganization the business will be continued.

Torrington, Conn.—In accordance with an action taken at a meeting held September 6, the E. A. Perkins Electric Company has increased its capital stock from $5,000 to $20,000. The company has bought the factory building owned by E. A. Perkins and two other storage buildings. No change has been made in the company and the new stock has been subscribed by the old stockholders. The company is putting in new machinery.

Warren, O.—The Packard Electric Company has reduced its capital stock from $40,000 to $10,000.

PERSONAL AND MISCELLANEA.

The Rev. Prescott Ford Jernegan has written to his parents at Edgartown, Mass., that he intends to leave his present residence in Belgium and return to America to make amends for his dealings with his fellow-men in the matter of sea-water gold and the Electrolytic Marine Salts Company, so far as he is able to do so.

John Lundie, an engineer formerly connected with the Illinois Central Railroad, has been appointed electrical expert of the Brooklyn Elevated Railroad, and will at once begin the work of preparing plans and specifications in regard to the change of motive power from steam to electricity on the Fifth and Lexington avenue lines of the company. As soon as the plans are in readiness and the specifications approved by the company's board of directors the various large electrical concerns will be asked to submit bids for the work.

Jacob Jatkowsky, the proprietor of a small dry goods store in Newark, N. J., was killed by an electric shock on Thursday night last. On closing up the store he and an assistant named Van Riper were carrying in a show case which had stood in front of the store, when the metal top of the case came in contact with a low-hanging electric light. Instantly the entire frame of the case became heavily charged with electricity and both men let go of it as the current entered their bodies. Van Riper, though dazed for an instant, was not knocked down. Jatkowsky, however, fell to the ground and lay motionless. Physicians were hastily summoned, but in spite of their attentions he died in a few minutes. The only marks caused by the electric current were a slight burn and abrasion of the skin on his right hand. One of Van Riper's hands was badly burned.

A trolley car of the Nassau Railroad, Brooklyn, on Tuesday evening of last week jumped the track at Rogers avenue and East Broadway, crashed through a wood fence, ran across Justice Curran's trim-kept lawn, and thrust a third of its length through the Judge's dining room window while the family were at dinner. They were badly frightened for the moment, but as no one was hurt, the ludicrousness of the intrusion soon set them all laughing. There were no passengers on the car, and the motorman and conductor jumped off when it left the track.

RECENT COMPANY ELECTIONS.

Albany Railway Company, Albany, N. Y.—Directors: Robert C. Pruyn, Anthony N. Brady, A. Bleecker Banks, John W. McNamara, James H. Manning, James McCredie, William McEwan, Elnathan Sweet, James Rooney, John G. Myers, S. W. Rosendale, Clarence N. Flack and William J. Walker.

Cayadutta Electric Railroad Company, Gloversville, N. Y.—President, J. Ledlie Hees; first vice-president, Thomas E. Ricketts, Johnstown; second vice-president, Alvah J. Zimmer, Gloversville; secretary and treasurer, George M. Place, Gloversville.

Columbia Traction Company, Harrison, N. J.—President, Franklin G. Simmons; treasurer, William C. Allen; secretary, Ernest B. Foster. The company, organized under the laws of New Jersey, is to operate an electric railway between the city of Hudson and the village of Philmont, N. Y., and furnish lights to the various municipalities through which the road will run.

Edison Electric Illuminating Company, Boston, Mass.—At the annual meeting on the 15th inst. the old officers and directors were re-elected with the exception of Director E. F. Whitney who has been succeeded by William Powell Mason.

Rockland, Thomaston & Camden Street Railway Company and the Knox Gas & Electric Company, Rockland, Me., have re-elected the old officers and directors as follows: President, George E. Macomber; treasurer, A. D. Bird; clerk, Herbert M. Heath; superintendent and manager, Thomas Hawken; directors: G. E. Macomber, John F. Hill, S. M. Bird, W. S. White, W. F. Cobb, A. F. Crockett and H. L. Shepherd.

Schuylkill Valley Traction Company, Norristown, Pa. (reorganization).—President, C. D. Beebe; general manager, secretary and treasurer, R. M. Douglass; superintendent and electrician, A. G. Davids; directors: C. D. Beebe, N. H. Larzelere, R. M. Douglass, Thomas Corday, D. B. Shepp, H. S. Holden and G. B. Leonard.

Standard Light & Power Company, Montreal, Can.—President, W. McLea Walbank; vice-president, J. H. Burland; secretary, E. Craig; directors: W. McLea Walbank, J. H. Burland, Peter Lyall, W. S. Evans, L. H. Heneault, F. Dagenais and M. P. Davis.

Utica & Deerfield Street Railroad Company, Utica, N. Y.—President and general manager, Frederick B. Weaver; secretary and treasurer, W. Pierrepont White.

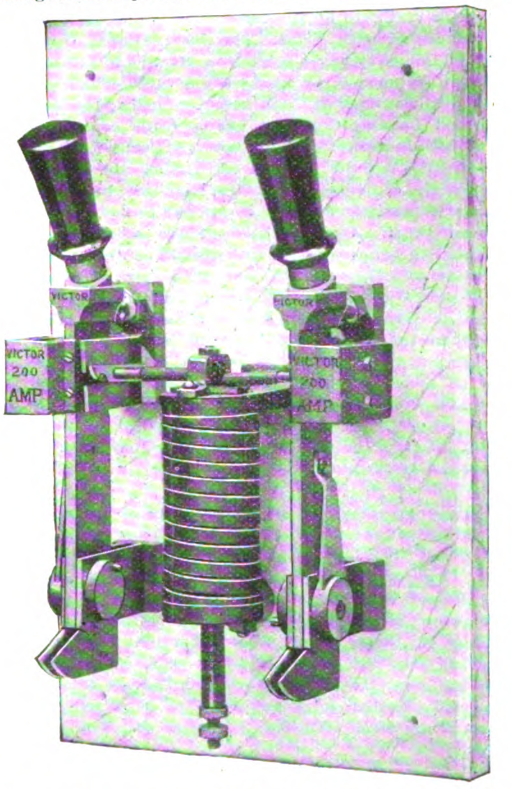
COMMERCIAL PARAGRAPHS.

A New Circuit Breaker.

Below we illustrate a new circuit-breaker which has been on the market for several months and has been used on some of the largest installations in New York City; it is worthy of mention owing to its many advantages over other circuit-breakers and the many new and novel features which are embodied in the construction of the instrument. The action is also new and radically different from any other instruments on the market.

This circuit-breaker is manufactured by the firm of F. A. LaRoche & Co., 13th and Hudson streets, New York City, who are also the manufacturers and owners of the "Ideal" circuit-breaker, which has heretofore been mentioned in the various journals. They also manufacture a full line of switches, switchboards and all kinds of switching devices.

The new circuit-breaker's trade name is "Victor," and the name is a very appropriate and deserving one. The style of this circuit breaker is of the fly-out action, but the danger to the operator is reduced to a minimum owing to



the shortness of the blades and the momentum being checked or broken as soon as the circuit is interrupted.

They are made of the independent action, that is to say, each blade is separately thrown in and controlled, and in case of a short circuit or overload both blades simultaneously open up, the action in that respect being similar to the well-known "Ideal" circuit-breaker, which was the first circuit-breaker put on the market with this novel feature.

Neither the "Victor" nor "Ideal" can be closed as long as the overload or short circuit exists in the line. As soon as the blade is thrown in, and you attempt to throw the opposite blade in, the blade already in the clips will open up independently of the blade being closed, thereby making it unnecessary to use knife-switches in conjunction with these circuit-breakers. Each blade has a separate latch and catch which acts on the roller principle, reducing the friction to a minimum. Also, each blade is independently hinged on a self-locking hinge post, which by the act of closing the blades compresses the blades of the hinge post, and which can be compressed to any degree, as this locking device is graduated and is adjustable, and can be set with a pressure of 1,000 pounds to the square inch of pressure between the clips and blades, therefore always making that a solid mass of copper.

It has never yet been known that any of these breakers became heated at the hinge post with double the amount of current passing through for what it is intended. The breaker is equipped with new style carbon breaks of liberal capacity, so adjusted that the blades have left the conducting clips one inch before the break taking place on the carbon, thereby preventing burning of the clips, freezing and cutting, which so often cause trouble with switches and circuit-breakers.

The solenoid is differentially wound, which concentrates the force to the hole of the solenoid, very little current passing through the outer coil. The coils on the circuit-breakers from 100 amperes up are wound with bare copper and carefully insulated, yet when the coil is completed it looks like one solid spiral of copper. It is as yet the neatest method employed in making coils for automatic switches. The entire circuit breaker is made up of cold hard-drawn copper, no castings being used throughout its entire construction.

The whole conducting parts of this circuit-breaker are calculated on a basis of 750 amperes to the square inch sectional area. Each blade has an independent plunger and copper steel spring, which can be removed if required from the front or back of board as may be desired.

Another advantage of this circuit breaker is the few number of holes that need be drilled in the switchboard—only seven holes being required to hold the circuit-breaker in place and on the board. The range of adjustment is large, namely, a circuit-breaker with a normal rating of 200 amperes can be adjusted to break a circuit anywhere between 100 and 400 amperes.

They are also made with underload attachment. Every one of these circuit-breakers is carefully and accurately calibrated, and they are as reliable as any ampere-meter on the market.

Large Orders for Spiral Riveted Pipe.

The great strength and durability of this style of water pipe, the ease with which it may be handled, and the fact that it is not liable to give trouble through leakages, has brought a steadily increasing demand for Root's Spiral Riveted Pipe.

The Abendroth & Root Manufacturing Company, 28 Cliff street, New York, sole manufacturers, report a number of large orders recently received.

To the Sheely & O'Shee Company, contractors, of Lincoln, Neb., they have lately shipped 12,000 feet of their pipe which will be used in extending the waterworks at Lanesboro, Minn.

About 10,000 feet have been sent to Milledgeville, Ill., and 15,000 feet to the city of Augusta, Wis.

The U. S. Water & Steam Supply Company, contractors, Kansas City, have placed an order with the company for about 5,000 feet of pipe which will be used at Concordia, Mo., and 6,500 feet are to go to J. L. White, contractor, Wyoming, Ill.

Removal Notice.

The general Eastern office of the Siemens & Halske Electric Company of America has been removed to the Land Title Building, Philadelphia, Pa. Their New York office for local business (metropolitan district) is now located at Room 511, Cable Building, 621 Broadway, New York City.

The Electric Appliance Company, Chicago, are calling attention to their new self-contained automatic hook. This hook is exclusively the Electric Appliance Company's design and manufacture, and a number of very strong claims are made for it. It is very easy to install and occupies very little space. It is put together complete and adjusted before shipping, and is therefore sure to reach the customer in good shape. The contacts are always visible upon opening the door, which makes it easy at any time to see that everything is in working order. The hook is constructed with a cam at the back to prevent the lever being bent back out of shape. This hook is apparently a very desirable article.

INCORPORATIONS.

The Electric Railway & Manufacturers' Supply Company, San Francisco, Cal. Capital stock, $50,000, of which $500 has been subscribed. Incorporators: Allan S. J. Boure, S. H. Taylor, Frank Frisble, Harry P. Bowie and H. S. Hagan.

The Sedalia Electric & Railway Company, Sedalia, Mo. Capital stock, $400,000. Incorporators: C. H. Reeve, J. C. DeLong, J. C. Van Riper, W. O. Evans and A. M. Trader.

The Cincinnati, Milford & Goshen Street Railway Company, Cincinnati—to build an electric or other railway between Linwood, in Cincinnati, and Goshen, Clearmont

County, running along the Cincinnati, Columbus & Wooster turnpike, through the village of Milford. Capital stock, $10,000. Incorporators: Frank A. Goodwin, Frederick E. Niederhelman, William C. Compton, Lennox C. Goodwin and S. W. Kittering.

ELECTRICAL PATENT RECORD.

Letters Patent Issued October 11, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

612,062. Trolley-Arm. Benjamin R. Shopp, Jr., Jersey City, N. J. Filed March 15, 1894.

612,068. Switching Mechanism. George W. Singleton, Syracuse, N. Y., assignor to Peter J. Ramion, John A. Henesey and Matilda E. Ramion, same place. Filed Jan. 18, 1897. Renewed March 5, 1898.

612,068. Electric Railway. Frederick D. Sweet, Elyria, O. Filed Nov. 22, 1897.

612,182. Electric Trolley Device. Charles L. Jeffrey, Johnstown, Pa., assignor to the Steel Motor Company, same place. Filed Jan. 12, 1898.

612,284. Electric Traction Apparatus. Raoul Demeuse, Brussels, Belgium. Filed July 23, 1897.

612,255. Trolley-Pole. Virgil A. Mason, Austin, Tex., assignor of one-half to Elizabeth Covert, same place. Filed April 20, 1898.

612,344. Underground Electric Railway. Charles W. Jenkins, Richmond, Va., assignor to Wilton F. Jenkins, same place. Filed Oct. 28, 1897.

612,351. Trolley-Wheel Support. Edwin Lane, Johnstown, Pa. Filed June 28, 1897.

612,021. Car-Fender. Cyrus Coplantz, Joliet, Ill., assignor to Hugh L. Coplantz and Frank E. Cheesman, same place. Filed May 31, 1898.

612,340. Car-Fender. Morris Hirsch, New York City. Filed March 13, 1897.

ELECTRIC LIGHTS AND APPLIANCES.

612,049. Arc-Lamp Globe. Henry G. Mills, Milwaukee, Wis. Filed May 10, 1897.

612,[illegible]. Casing for Electric Car-Lighting Apparatus. Willard F. Richards, Buffalo, N. Y., assignor to Charles M. Gould, same place. Filed Nov. 26, 1897.

612,152. Electric-Lamp Socket. Frank M. Bell, New York City, assignor of one-half to Wilma Pollack, same place. Filed Jan. 10, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

612,015. Lightning-Arrester. Cummings C. Chesney, Pittsfield, Mass., assignor to John F. Kelly, same place. Filed Jan. 15, 1898.

612,038. Electric Switch. Gerald W. Hart, Hartford, Conn., assignor to the Hart & Hegeman Manufacturing Company of Connecticut. Filed Oct. 28, 1896.

612,122. Electrical Converter. Ferdinand Schwedtmann, St. Louis, Mo. Filed Aug. 28, 1897.

612,146. Electric System of Distribution. Joseph N. Thomas, Johnstown, Pa., assignor to the Johnson Company, Lorain, O. Filed Feb. 15, 1898.

612,192. Hinge Conductor for Electric Currents. Frank E. Chandler, Brandon, Vt. Filed Jan. 8, 1898.

612,208. Controlling-Switch for Electric Motors. Reese Hutchison, Mobile, Ala., assignor of three-fourths to James H. Wilson and Joseph A. Maloney, same place. Filed Feb. 17, 1898.

612,212. Rheostat. Edwin O. Raster, Chicago, Ill., assignor to the Raster Carbon Rheostat Company, same place. Filed April 11, 1898.

TELEPHONE AND TELEGRAPH APPARATUS.

612,172. Telephone Arm-Rest. James R. McKelvey, Lawrenceville, Ga. Filed Aug. 23, 1897.

612,219. Telephone Central Station Apparatus. Julius H. West, Berlin, Germany. Filed July 8, 1896.

612,286. Circuit-Controller and Receiver-Support. Luis Duque, Paris, France, assignor, by direct and mesne assignments, of two-thirds to Addison Bybee, Chicago, Ill., and H. E. Freudenthal, Pioche, Nev. Filed Aug. 21, 1897. Renewed June 9, 1898.

612,330. Telephone Pay-Station. William Gray, Hartford, Conn., assignor to the Gray Automatic Telephone Pay Station Company, same place. Filed Nov. 21, 1895.

MISCELLANEOUS.

612,009. Process of and Apparatus for Electrolyzing Sea-Water. Giovanni B. Baldo, Triest, Austria-Hungary. Filed Oct. 5, 1896.

612,250. Process of Electrolytic Separation of Metals. Heinrich von der Linde, Crefeld, Germany. Filed Nov. 19, 1897.

612,326. Electric Battery. Manes E. Fuld, Baltimore, Md. Filed Aug. 4, 1897.

RE-ISSUE.

11,697. Conduit-Outlet Insulator. Frederick W. Erickson, Boston, Mass., assignor of one-half to Eric E. Erickson, same place. Filed June 25, 1898. Original No. 566,507, dated Aug. 25, 1896.

TELEPHONE AND TELEGRAPH.

A New Opposition Telephone Company.

On Wednesday last the People's Telephone Corporation of New York filed articles of incorporation at Albany, and it is asserted that they have already acquired a franchise and have the capital necessary to equip exchanges, lay wires and supply 40,000 or 50,000 subscribers with new and improved instruments. The company is formed as a result of the agitation against the alleged exorbitant charges of the Bell Company in New York, and has at its back the Board of Trade and Transportation, who have vainly fought for legislative aid in getting lower rates at several sessions of the Legislature. Mr. Frank S. Gardner, secretary of the board, has publicly explained the purposes of the new organization. He says the new company intends to cut the unlimited service rate, which is now $240 per year in Manhattan, to $100, and the present minimum rate of $90 for 600 messages to $40 for 400 messages. The residence message rate for service on private wire is to be $30, and families living in apartments and flats are to be furnished with an unlimited service on group lines for $1 per month. In Brooklyn, the unlimited service rate of $150 is to be cut to $75. The inter-borough charge is to be cut to five cents per message. The company will guarantee that such rates shall continue five years. Connections for long distance telephones are also to be made. The officers of the company, elected Thursday last, are: President Darwin R. James, president of the Board of Trade and Transportation; vice-president, Elias S. A. de Lima, of the commission firm of D. A. de Lima & Co.; secretary, Frank S. Gardner; treasurer, Silas B. Dutcher, president of the Hamilton Trust Company.

In Cuba telegraphic communication exists between the different interior towns and principal villages over lines that were erected by the Spanish Government, erected in the rudest fashion, many of the wires resting on trees without the vestige of an insulator. There are four cable lines connected with Cuba. The International Ocean Telegraph Company has a cable from Havana to Florida; the Cuban Submarine Company has a cable connecting Havana with Santiago de Cuba and Cienfuegos; the West Indian and Panama Company has a cable connecting Havana with Santiago de Cuba, Jamaica, Porto Rico, the Lesser Antilles and the Isthmus of Panama; the Compagnie Francaise de Cables Sous-Marins has a line connecting Havana with Santiago de Cuba, Hayti, San Domingo, Venezuela and Brazil. An English cable between Santiago de Cuba and Cienfuegos connects with a land line giving communication with Havana. The only three towns in Cuba having cable connections are Havana, Cienfuegos and Santiago de Cuba. The Statesmen's Year Book for 1898 is authority for the information that there are 2,300 miles of telegraph line with 153 offices in Cuba. The principal towns in Cuba are lighted by electricity, as are also the greater number of the sugar estates. There are about 475 miles of telegraph lines in operation in Porto Rico, and submarine cables connect San Juan with St. Thomas and Jamaica.

At the annual meeting of the stockholders of the Home Standard Telephone Company held at Albany, N. Y., on the 11th inst., the following officers and directors were elected: President, John M. Bailey; vice-presidents Henry Russell and James Rooney; treasurer, Howard Hendrickson; secretary, Charles L. A. Whitney; directors: John M. Bailey, Henry Russell, John A. McCarthy, John H. Farrell, William P. Rudd, Charles L. A. Whitney, James B. Lyon, Howard Hendrickson, James Rooney, Ten Eyck T. Mosher, John Wagner, Wm N. S Sanders, Thomas W. Cantwell, William H. Keeler and Frank B. Delehanty.

Judge John A. Williams of the U. S. District Court has issued an order restraining the city of Helena, Ark., from enforcing an ordinance regulating the rates of the Southwestern Telegraph and Telephone Company which the council passed recently. The ordinance makes the rates for telephone service $1.50 per month for residences and $2.50 for business offices. The passage of the ordinance was fought bitterly by the company, which claims that the constitution does not permit a city council to regulate its rates. On the other hand, the city sets up the fact that the same company is furnishing other cities in the State, namely, Little Rock, Pine Bluff and Fort Smith, with the same service at even lower rates, and they simply want to be treated as other towns are. The case will be fought to a finish in the courts.

The subscribers to the telephone service of the Chesapeake and Potomac Telephone Company in Washington, D. C., met a few evenings ago in Willard's Hall and formed a permanent organization for the purpose of providing ways and means to prosecute the suits brought against the company to enforce compliance with the recent Act of Congress regulating the rates for telephone service in the District of Columbia. At the conclusion of the speeches it was decided by unanimous vote that the subscribers who pay $100 or over for the use of a telephone shall pay $5 monthly into the association's fund, and those who pay less than $100, $2.50 per month. In addition to those who were already contributing members, thirty-five new members signed.

The executive committee of the National Association of Fire & Police Telegraph Superintendents and Municipal Electricians met at Wilmington, Del., on the 8th and 9th inst., to consider arrangements for the convention of the association next year which is to be held in Wilmington. The Board of Trade appointed a committee to assist in entertaining the visitors. The tug Laura B. was chartered to take them on a trip down the river and a dinner was provided for them at Delaware City. Everything conspired to make their visit a pleasant experience. The principal work of the committee was revising the by-laws of the association and discussing arrangements for the next annual meeting, one of the features of which will probably be an exhibition of electrical supplies.

The Conway Telephone Company is now building a line from Tishomingo, I. T., to Denison, Tex. The line is constructed as far as Emet and will come down the Washita river from there to Linn, from Linn to Cumberland, Cliff, Grantham and small towns in that section, then across country to Mead and to Colbert and from Colbert to Denison. This is an extension of the line that now runs from Tishomingo to Oakland and from Oakland to Ardmore. It will connect every town in the Chickasaw nation by telephone in the near future, and it is expected that it will be in operation into Denison by the middle of December or perhaps before that time.

The New Telephone Company of Indianapolis has been granted a franchise in Anderson, Ind., and has made a contract with the Overshimer company of Elwood, an independent organization, by which all patrons of the latter may use the New Company's toll lines. The New Company expects to have its Anderson exchange in operation before the 1st of January.

A representative of the Mutual Telephone Company addressed the council of Waterford, Pa., at its last meeting, laying before them a scheme for the establishment of a local telephone exchange. The members were favorably impressed, and an ordinance will be introduced at the next meeting granting him a franchise.

The West Virginia Telephone Company has been granted a franchise in Sistersville, W. Va. The old McGhie & Moore line, which has been in operation about six months, has been ordered removed and the new company will get full possession of the field.

The Pan Telephone Company has resumed operations at Fort Smith, Ark., having purchased the plant from L. E. Ingalls which had been sold to him by Col. James Brizzolara who had obtained it by purchase at a judgment sale to satisfy a claim of Ingalls against the original company.

The franchise of the Atlanta Telephone Company to build, equip and put in operation a new telephone system in Atlanta, Ga., has been extended until May 1, 1899. The extension was granted by the general council.

The ordinance of the Chattanooga council granting J. A. Helvin a franchise for the establishment of a new telephone system in that city has been renewed and extended to February 1, 1899.

The Drawbaugh Telephone & Telegraph Company of Philadelphia has filed plans for its proposed system in that city with the Board of Highway Supervisors.

New Companies Incorporated.

The Panhandle Telephone Company, Moundsville, W. Va. Capital stock, $50,000.

The Thomasville Telephone Company, Thomasville, N. C.—to establish a telephone system in Thomasville and surrounding country. Capital stock, $6,000. Incorporators: F. S. Lambeth, J. W. Lambeth, C. A. Julian, J. F. Haden and others.

The Grand Prairie Telephone Company, Hazen, Ark. Capital stock, $10,000, of which $1,000 has been subscribed. Incorporators: Geo. D. Foster, J. G. Thweats, J. M. McClintock, A. L. Aydelott, David Brockaway and others.

The People's Telephone Corporation of New York—to operate a telephone system in New York City and in other cities, towns and villages in New York and other States and in the Dominion of Canada. Capital stock, $5,000,000, divided into $2,000,000 preferred and $3,000,000 common stock. Directors: S. B. Dutcher, J. E. Nichols, E. S. A. De Lima, Francis C. Travers, Frank Brainard, J. Fred Ackerman and Darwin R. James of New York City.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12@12⅛c.; Lake, 12⅜@12½c.; casting, 11⅞@12c.

The Brooklyn (N. Y.) City Railroad Company declared a quarterly dividend of 2½ per cent., payable October 15.

The North Chicago Street Railway Company has declared a dividend of 3 per cent., payable October 15 to stock of record October 5.

A dividend of three-fourths of 1 per cent. was paid by the Little Consolidated Street Railway Company of Cleveland, O., on the 8th inst., for the quarter ending October 1.

The Phoenix Carbon Company of St. Louis has filed notice with the recorder of deeds in that city of an increase of capital stock from $160,000 to $500,000. The assets are given as $447,050.90 and liabilities $80,746 26.

H. E. Huntington and his associates have purchased the San Mateo Street Railway at Los Angeles, Cal., and also the street railway franchises, covering many streets in the city, owned by J. C. Kays. The syndicate already owned the greater part of the entire street railway system of the city.

The Court of Appeals, in the tax case of the Edison Electric Illuminating Company of Brooklyn, N. Y., has sustained the Special Term and the Appellate Division of the Supreme Court in that borough in their decision that the State has no power to tax a patent for an invention granted by the United States.

The directors of the Chicago Edison Company have declared the regular quarterly dividend of $2 per share, payable November 1 to stock of record October 5. The gross earnings of the company for the six months ended September 30 show an increase of approximately 20 per cent. The net receipts show an increase over fixed charges of between 11 and 12 per cent.

The Columbus (O.) "State Journal" says: "The installation of a new telephone system is being secretly agitated in the city of Columbus. It is said that enough prospective customers have been approached on the subject to indicate that the scheme will be successful. Rentals will be $36 for a business telephone and $25 for a private telephone per year."

According to the charter of the People's Telephone Company of New York the preferred stock will be entitled to 8 per cent. cumulative dividends before one on common shall be declared. The preferred is subject to redemption after five years at 110. Each of the directors has subscribed for 1,200 shares of the $5,000,000 stock. The company expects to have its plant in operation in about a year.

Spencer Trask & Co. and Vermilye & Co. offer at 93½ and accrued interest the unsold balance of $2,000,000 Edison Electric Illuminating Company of Brooklyn first consolidated mortgage 4 per cent. bonds, at which rate they will pay about 4 35 per cent. These bonds are part of $10,000,000 bonds authorized under the mortgage, but the present issue will be for only $2,000,000, the proceeds of which will be applied for the payment of the Municipal Company's stock.

On the 14th inst. the New England Telephone & Telegraph Company successfully opened long distance telephone communication between Boston and Kansas City, a distance of 1,560 miles, which marks the farthest advance yet in the science. This is thought to be near the extreme limit of successful transmission through the telephone and longer distances are only expected when some repeating system is devised. Conversation at this distance between the two cities was clearly audible.

Mr. E. L. Carr, treasurer of the United Electric Securities Company, Boston, has kindly sent us an note correcting an item which appeared in this column last week. He says: "On page 224, under 'Notes for Investors,' the United Electric Securities Company is on record as having retired $20,000 of its eighth series collateral trust 5 per cent. bonds at an average price of 102.925, leaving 236 still outstanding. This is an error, as the person who offered to sell us these bonds found on examination that his were not eighth series bonds."

The Edison Electric Illuminating Company of Boston has declared a regular quarterly dividend of 2 per cent., payable November 1. It also changed its fiscal year to end with June. For six months the report shows gross earnings of $488 964; expenses, $306,850; net, $182,113. The balance sheet shows: Cash on hand, $106,-846; profit and loss surplus, $25,343. The number of incandescent lamps connected June 30, 1898, was 161,466; arc lamps, 1,486; motors, 6,413 horse-power; compared with 138,682 incandescents, 1,446 arc, and 5,675 horse-power June 30, 1897.

The debenture certificates for 12,000 shares of the capital stock of the Narragansett (R. I.) Electric Lighting Company, to issue which the stockholders on the 8th inst. authorized the directors, are to be subscribed for on or before October 20. These certificates will not bear interest, but at the end of four years they can be exchanged for capital stock, the par of which is $50. Every stockholder of record October 8 is entitled to subscribe for one share of the new stock for every two shares now held—that is, if he has ten shares he may subscribe for five new ones at par, or he may sell his rights to the new issue. These rights have been listed on the Providence Stock Exchange.

The New York "Mail and Express" states that it failed to get an answer from the receiver of the Staten Island Rapid Transit Company to the question why with net earnings three times as large as the interest on the first mortgage bonds the road had defaulted on the October interest. The same paper says: "Two committees are industriously seeking bonds with a view to protecting the interests of the bondholders. Dick Bros. & Co. are at the head of one committee, and they are so certain of compelling the company to pay the defaulted coupon that they have been advancing the amount of the interest to stockholders depositing bonds with them. The other committee merely gives receipts for the bonds. It consists of J. W. Davis, T. Denny, Jr., and F. J. Lisman."

The Manhattan Railway Company (elevated) of New York is reported to have practically completed its plan for the electric equipment of the system, and may perhaps submit it to the stockholders at the annual meeting on November 9. The payments for damages to abutting property made by the Manhattan Company amount to date to the astounding aggregate of $13,238,715, or equal to 8.79 per cent. of the gross passenger earnings during the past nineteen years. The amount paid for this account for the year 1897-98 is stated as $861,450, contrasting with $890,281 in 1896-97, $952,296 in 1895, and as high as $1,058,642 in 1890-91. These items are included in the company's construction account.

The New York Gas & Electric Light, Heat & Power Company, the new $25,-000,000 concern recently incorporated at Albany, is causing as much speculation as to its purposes in Boston as in New York. The Boston "News Bureau" says: "It is the guess of some that the new company, counting upon its close relations with city officials, will proceed to install a large plant in opposition to all of the old companies and then precipitate a fight on rates in order to rapidly extend its business and to finally secure control of the whole lighting situation as was done in Brooklyn. In such a case there is certain to be a contest, with the Edison Company backed by the General Electric Company and the Morgan people. It is not improbable that some knowledge of the approaching contest led the Edison Company to bid for popular favor by issuing its recent circular naming lower rates for light and power service, which act is looked upon in some quarters as the inauguration of a fight which will lead to combination against combination, the outcome of which will be awaited with unusual interest by Bostonians, who are largely interested in the situation." The New York "Post" says that one of the parties interested in the new company states that it will have no plant of its own, its purpose simply being to distribute the excess of electric power of the plants of the Brooklyn Rapid Transit and Metropolitan Railway companies.

EDITORIAL NOTES.

Lighting of Cities.

The city of Boston has of late been examining into the subject of municipal lighting. This important question has been taken up and dealt with very thoroughly, and the conclusions reached and general information gathered may prove of interest to other large municipalities. The problem to be solved was whether the city should renew the lighting contracts with outside companies, which were about to expire, or undertake to operate a municipal plant. A lengthy report dealing with this subject was submitted to the Board of Aldermen by ex-Mayor Matthews, in which he looks at the question from every possible standpoint, and compares the cost of lighting in a number of other cities with that obtaining in Boston. The total number of lights in operation nightly in that city is 2,365, of which 1,506 are operated by means of the overhead system and 538 supplied by underground mains. Besides these there are 321 lamps for park lighting. The price charged for each of the street lights is 35 cents a night and for the park lamps 34 cents, making the average price per light per annum $127.25. As shown by the report, this price compares very favorably with the cost of lighting by the municipal plant in Detroit, which is $134.57 a year for light under conditions prevailing in Boston, or with the Chicago municipal plant whose lights cost $154.80 a year. The price in St. Louis is $99.67 and in Cincinnati $110.89 a year, while the average prices in Philadelphia and New York are $143.33 and $139.90 respectively. In his report, referring to the prices charged, Mr. Matthews reaches the following conclusions:

"(1). That the prices now charged in Boston, namely, $127.75 for street and $124.10 for park lights per annum, are, if the company supplies the entire machinery and fixtures (including lamp-poles), except the circuits within the limits of the several parks, on the whole and taking into account all the differences in local conditions that are capable of being represented in dollars and cents, slightly lower than the cost upon a commercial basis of the lights furnished by the municipal plant in Detroit, considerably lower than the cost upon a commercial basis of the lights furnished by the municipal plant in Chicago, considerably lower than the prices charged for street lights by the private companies of New York, Philadelphia and Baltimore, and about the same as the prices charged by the private companies of Chicago.

"(2.) That these prices are, taking the same considerations into account, considerably higher than the prices charged for street lights by the private companies of St. Louis and Cincinnati, and slightly higher than those charged by a private company for park lights in Baltimore.

"(3.) That the St. Louis price is too low to cover depreciation or profit was agreed to by persons more or less ignorant of the business; caused or helped to cause the failure of the company and the foreclosure of its property; and that the contract when it expires will probably not be renewed except at a higher figure.

"(4). That the Cincinnati price, assuming that the lights are full 2,000 candle power, is due to the fact that the company has a long contract during which the lights are to be increased to a total of 4,000, or about twice as many relatively as Boston; and that, even after allowing for this fact, the price is probably too low to cover depreciation and profit."

Mr. Matthews concludes his report by recommending that a new contract be entered into with the lighting company, with the understanding however that the latter shall agree to furnish all the latest improvements and cheapening devices, and furthermore that every increase of 250 in the number of lights the price be reduced by one-half cent per night until 30 cents per night is reached. It is also suggested that the price of lighting be regulated, and thus the city's interests guarded, at comparatively short intervals by means of an arbitration committee composed of three members, one appointed by the city, the second by the lighting company and the third by the persons thus selected.

That municipal lighting plants are by no means economical was never more forcibly brought out than in this able report, and the city of Boston is to be congratulated on adopting a wise course and avoiding following in the footsteps of either Detroit or Chicago.

* * *

The Metric System.

This country is to-day, so to speak, stepping across the threshold of a new national career. The coming of the 20th century will find us grasping for the trade and commerce of the world. In order to secure this trade we must bid for it in terms that will be understood by the majority of nations. We must carry into the struggle no load of antiquated systems or inconvenient and cumbersome methods. For this reason it is believed that the adoption of the metric system of weights and measures would be an advantage and stimulus to our foreign commerce as well as a saving of both time and labor.

During the coming session of Congress attention will therefore be called to the fact that the present system of weights and measures militates seriously against our trade with foreign countries, owing to

the fact that American price lists are more or less confusing to foreign merchants. It will be further pointed out that the metric system, by reason of its decimal scale, its simplicity, its international character, and its unquestionable superiority to any other system of weights and measures, is worthy of universal adoption, and there will be a strong effort made to secure the enactment of a bill making it obligatory on the Government in the conduct of business to use this system. This bill was up at the last session, but failed to reach a vote. As the country has extended its boundaries since that time, as well as changed its position relative to other powers, becoming more of a factor in the affairs of the whole world, the passage of the bill should be urged not only on the old grounds, but for the new reasons to be found in the results of the war with Spain.

The advantages of the proposed system are twofold: First, it is international in character, and almost universally in use among civilized nations, and secondly, the metric system from its decimal character is convenient and economical in practical use.

Beyond the adaptation of the metric system to the economic transactions of the ordinary affairs of daily life, it has a claim to respectful consideration as being the language of science the world over, used in scientific investigation and understood by scientific men in every nation and clime. That its use unquestionably tends to accuracy and precision of thought and expression is not to be doubted. The simplicity of the system, or its "oneness," to use the word coined by Lord Kelvin, is one of its great merits. It has but one system for every kind of weight and measure, and the method of written expression is the one of ordinary numerical notation. The fundamental unit is the meter, and from that are derived by the simplest process not only measurements of extension, but of weight and capacity as well. The conversion of bulk to weight and weight to bulk requires but a knowledge of specific gravity. It has been claimed by some that the difficulty of changing from our present tables of weights and measures to the metric system would be enormous. Lord Kelvin once expressed his views on this subject in the following language:

"I believe that the difficulty of making the change has been enormously exaggerated. I believe that in a fortnight people would become so accustomed to the perfect simplicity and easy working under the metrical system that they will feel that instead of its being a labor to pass from one system to the other, it will be less than no labor—that is to say, it would be a very great saving of labor after the first day or two of beginning to use the metrical system." Mr. Siemens, the noted engineer, testifying as to its introduction into his works, says: "It was all a matter of about a fortnight or three weeks; then the people were accustomed to it and did not ask any more for the old measures, but asked for the new."

This is a matter of the greatest importance to the electrical fraternity. There is no doubt but that the adoption of such a system would have a material bearing on our export trade, and what industry is more interested in this important subject than the electrical industry?

* * *

Up Mont Blanc by Railway and Elevator.

Of recent years, or since the development of electricity for power purposes, many mountain railways have been built in seemingly inaccessible places. We refer especially to such lines as that of Burgenstock, near the Lake of Lucerne in Switzerland, which reaches a height of 2,600 feet in a distance of 2,700 feet, and to those at Strauserhorn, in the same locality, with grades ranging from 30 to 62 per cent. The construction of the Jungfrau railway is another, and perhaps the best example to be cited in this connection, for it is an engineering achievement which but a few years back would have been impossible of accomplishment. These difficult undertakings have been brought to a successful issue, or, as in the case of the Jungfrau railway, ultimately will be, principally by an extensive use of electrically operated machinery and by taking advantage of any suitable water power in the vicinity for generating electric current economically.

Of late a mountain railway scheme has been mentioned, however, which for daring far exceeds anything that has yet been attempted. A French engineer of Marseilles has suggested a plan which he considers feasible for reaching the top of Mont Blanc, the highest mountain in Europe, whose summit is nearly 16,000 feet above the level of the sea. The scheme as worked out by this French engineer contemplates the building of a rack railway from what is known as Les Houches, a station on the line of the Geneva-Chamouni Railway, to a plateau on the side of Mont Blanc at an altitude of 6,888 feet, from which point a fine view of the Arve valley may be obtained. The line would rise 3,488 feet in a distance of 5,886 feet, or have an average grade of about 60 per cent. The necessary electric power for operating the road would be obtained from a waterfall on the upper Arve. The next step would be the running of a tunnel into the side of the mountain, starting from the plateau on which the rack railway terminates. This tunnel would have a rise of but 600 feet in 18,864, and would terminate at a point 7,500 feet above sea level, directly under the summit. So far there would seem nothing impossible in the plan suggested, although its accomplishment would be a more or less difficult engineering feat and cost an immense sum of money.

The next step, however, is probably the boldest suggestion made for some time. This is the piercing of a vertical shaft from the point where the tunnel ends to the summit of the mountain. The highest portion of this tunnel would have an elevation of 7,500 feet, and as the elevation of the summit is 15,800 feet the shaft would have to be 8,300 feet in length, or almost 1.6 miles. Many very deep shafts have been sunk for mining and other purposes, but invariably in such cases the work has been prosecuted from above, whereas in this case the shaft, which would be 10 by 12 feet, would have to be excavated from below upward. To meet this condition the promoter is said to have devised what he terms a "rising chamber," made of steel plates and constructed in two stories, each of the latter being divided into two compartments separated by heavy steel doors. In the upper story would be located the drilling apparatus. To avoid lowering the chamber out of the way of blasts, which would be impracticable and consume too much time, it is proposed to drill only on one side of the shaft at a time. Just before firing the blasts the drilling machinery would be moved to the neighboring chamber and the steel door closed to protect the inmates and machinery from pieces of flying rock. To catch the latter there would be a series of gratings placed at an angle of about 45 degrees and protected by fascines of brushwood. The rock thus collected would be transferred to the lower story, where it would be passed through suitable machinery, pulverized, and dropped down a 12-inch tube to the bottom of a shaft. Here a stream of water propelled by centrifugal pumps would carry it to the outer end of the tunnel. As the work progressed the chamber would be raised by means of steel racks placed in the four corners of the shaft. When completed the elevator would be operated by electricity. The scheme is unquestionably well thought out, and there is not a doubt but what part of it at least is feasible, providing sufficient capital could be obtained. Whether a shaft over a mile and a half in length could be excavated working from the bottom up, and whether an elevator could be made to run in it successfully or profitably if ever completed is another question and one we have our doubts about.

Under the Searchlight.

Notes and Comments on Various Topics.

In speaking of the proposal to equip the Manhattan road of New York (the elevated railroad) with electricity, one of the directors is reported as saying that no contract was likely to be signed for some time to come. The company wants the best system that it can find, he said, and it will not care to hurry in the matter of letting a contract for $6,000,000 or $8,000,000. It was stated that when the directors did finally ask for bids only one division of the elevated road would be equipped, so that this may receive a fair trial before the motive power on the entire road is changed.

* * *

A San Francisco man is said to have recently invented what is termed a "healthshaker." The machine consists of a platform on which the subject stands and which is then rapidly made to oscillate by means of an electric motor. The motion is said to be excellent for the liver, and the inventor claims that ten minutes of such shaking is better than half an hour's work in the gymnasium. A course of such shaking might advantageously be taken as a preliminary to a sea voyage.

* * *

It may interest some of our readers to know that telegraph and telephone poles are now being manufactured out of paper. The pulp from which these poles are made has mixed with it borax, tallow and other ingredients. It is then run into a mold with a central core and comes out as a hollow tube of the proper diameter and length. Before being erected the poles are given a coat of paint or varnish which makes them waterproof and very durable. If so desired, they may also be made fireproof by being saturated with a solution of alum water.

* * *

The *Herald* reproduces from its European edition the following as an instance of German red tape: "Some days ago, says the *Oberschlesische Volkstimme*, a schoolboy in Gleitwitz went out to fly his kite. A few minutes after its ascent it catches on the wire of the electric fire alarm and remains hanging. This catastrophe is seen by a vigilant policeman, who at once makes a report in writing to the Police Commissioner. The latter peruses the report and forwards it to the Police Inspector. The Inspector forwards it to the Town Hall, whence it reaches the Fire Committee of the municipality. The latter orders the kite to be removed, and moves a resolution that the zealous policeman receive a reward of 25 pfennigs. A fireman reports in writing that the kite has been removed. The cashier of the municipality pays the policeman 25 pfennigs and takes a receipt for the amount. The director of the school receives an order to find the boy who flew the kite—the search occupies fourteen days—and reprimand him. The rector reports in writing that this has been done. The Fire Committee sends a long document to the School Committee, requesting them to order the district school inspector to draw attention in all the schools under his orders to the danger of flying kites near telegraph wires, and forbidding them to indulge in this amusement in the streets of the town."

* * *

Philadelphia is in the midst of her great Peace Jubilee, which began on Tuesday with a naval review in which several noted war vessels took part, will be continued on Wednesday by the rededication of Independence Hall and a civic parade, and conclude on Thursday with a military parade and reception to the general officers at the Academy of

Music. Extensive electric illumination will enable everybody to see how the Quaker City looks at night while in the throes of a three-day celebration.

* * *

A WRITER in an Eastbourne (Eng.) paper, who is apparently of the Rip Van Winkle tribe, waxes eloquent over the coming of the Electric Age, though he gives the usual warning against "raw haste, half-sister to delay," and such like. Finally, he bursts into meter—of a kind—concluding with the following inspiring couplet:

"And dull reactionaries should remember, ere too late,
The Electric Age is coming—*and they can't postpone the date!*"

The italics are his. "All this," says *London Lightning*, in explanation, "is because the town council of a flourishing watering-place have decided upon going through with an electric lighting scheme, some three years after the cautious British public has found out that it is profitable in all senses, and Heaven knows how long since America and Continental Europe have had cheap light, cheap telephones and cheap tramways to an extent undreamt of here until quite recently. Surely it would be more correct to say that the Electric Age has come, though Eastbourne is only just awaking to the fact."

* * *

THE following recently appeared in the New York *Sun*:

"Tell me this," said the man from Chicago to the New Yorker, "who pays for lighting your streets when it is done? Who is the man or corporation who holds the Columbus avenue job? I live just off that thoroughfare, not far from Central Park. One reason I ask is that I think an old friend of mine who died seven years ago has returned to business and secured a contract in New York.

"His name was Baldwin. He was a Colonel in the civil war. When Carter Harrison the elder was first elected Mayor he appointed Baldwin gas inspector, and as long as Carter was Mayor the Colonel had the job. He was a faithful servant. He used to do his own inspecting on horseback. Many a night he played the solitary horseman act in Chicago, riding all night to see that the streets were properly lighted or darkened as he desired. For there were times when it was quite as important to turn off the gas as it was to turn it on at other times. One of the Colonel's imperative orders was that no gas was to be burned in the street lamps when there was moonlight. If the moon came up after, say, 10 o'clock, the street 'glims' were to be doused, or whenever it came up, no matter what the hour might be. And when the moon was in its first quarter the lamp-lighters used to watch it until it went down and then they lighted up.

"There never was a man who had the phases of the moon down as fine as Col. Baldwin. Cloudy weather cut no figure with him. The clouds might be thick enough to plough in, but as long as Col. Baldwin knew the moon was up and attending to business the streets were kept dark. For, the Colonel used to say, the moonshine was liable to break through any minute. Chicago saved money under old Carter Harrison's administration out of the moon as she was run by Col. Baldwin.

"But if the Colonel has come back and has a contract in New York, he has reversed himself. I find when I go home in the morning, when the moon is at its brightest, that the arc lights in Columbus avenue are doing their best work. But when there is no moon, and particularly when the clouds are thick and black, nary an arc light, nor any other kind, can you find. If a New York man has the contract he doesn't understand his business. If there is any moonshine in his contract he ought to stand in with the moon the same as old Col. Baldwin did, in the interest of the treasury and for the benefit of the populace."

The Electric Light in the Bengal Mills.

Almost all the jute mills, says *Indian Engineering*, are now lighted with electric light, and the special inspector reports that, with two or three exceptions, mills that had previously opposed its introduction have since been compelled to give way by the necessity of competing with their neighbors and retaining their hands, who otherwise would be attracted by the slightly higher wages they could earn by longer work elsewhere. In the report for the year 1896 the opinion of Mr. Walsh was quoted to the effect that working for the longer hours made possible by the use of artificial light was in reality a doubtful advantage, in view of the discontent caused among the operatives, the deterioration in the work done, and the higher wages to be paid for overtime. The facts now reported would appear to conflict with the view then expressed.

Street Railways of Glasgow.

The section of the Glasgow Corporation street railways recently equipped for overhead traction was formally inaugurated on October 13. This line is about 2½ miles in length and extends from Mitchell street to Springburn, the power station being situated near the suburban terminus. The line is double tracked throughout, and has been equipped on the span-wire system for an experimental trial of electric traction, prior to decision as to adoption of the overhead trolley for the entire system of street railways in Glasgow.

Electrical Industry in Egypt.

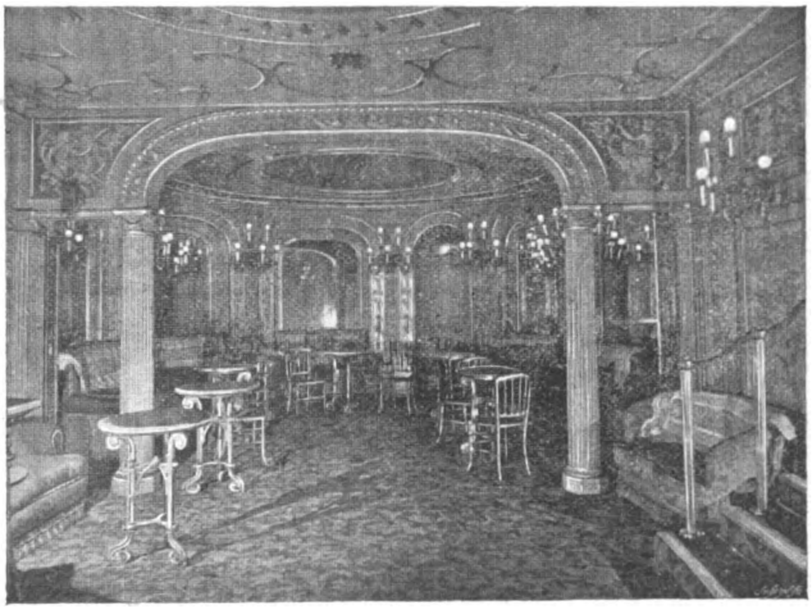
Considerable progress has been made during recent years in the electrical industry of Egypt. In Cairo electricity is used both for lighting and traction, as well as, of course, for transmission of messages. The Compagnie Centrale d'Eclairage par le Gaz have a monopoly for the supply of lighting and power in Cairo. Several private residences, however, together with public establishments, have private plants for electric lighting. For example, the palaces of the Khedive at Abdeen and Khoubbeh, Lord Cromer's residence, the Opera House, the Egyptian Railway Administration, several of the leading railways and Messrs. T. Cook & Son's Nile steamers. In Upper Egypt electricity is used in the sugar factories at Hawamdiyeh, Sheikh Fadl and Nag Hamadi. In Lower Egypt a large number of cotton factories are equipped with private electric generating plant, nearly a dozen districts having factories equipped in this way.

An Electrical Omnibus.

An electrical omnibus has lately been put in service experimentally in Berlin. According to a German contemporary, the 'bus has accommodation for twenty-six passengers, measures 23 ft. in length by 6½ ft. in width, while its weight, including the battery, is 6.65 metrical tons. The battery, which consists of 120 cells, contained in twenty-four boxes, weighs about 1¾ tons, and is stated to have a capacity sufficient to run the vehicle a distance of 60 kilometers (37½ miles) at a speed ranging from 6 to 12 kilometers per hour. The motor is geared to the front axle of the omnibus.

THE LIGHTING OF A THEATER.*

With the extension of public lighting mains into almost every part of London, it is not surprising to find that private plant for theaters and similar buildings is fast disappearing. There is much to be said against a theater operating its own lighting plant, but even in these days of public supply there is still something to be urged in its favor. To obtain a supply from the public mains means that it is not necessary to keep so large and so skilled a staff as would be necessary if a private plant were employed; no trouble from vibration is likely to occur in the theater or be transmitted to adjacent buildings, and there is under most circumstances probably less liability of a theater being plunged into darkness. On the other hand, a private plant, if skilfully operated, will supply current at infinitely lower rates than are offered by public companies, and lends itself better to those special stage effects that can be only created by the throwing on and off of large currents of electricity. This is especially valuable at times of rehearsal, when occasionally a heavy demand for current may arise. Moreover, it gives two strings to one's bow, for even with a private plant the usual practice is to be connected up to the street mains, and thus a prolonged and total extinction of light is less likely to occur than if a theater relied absolutely on the public mains.



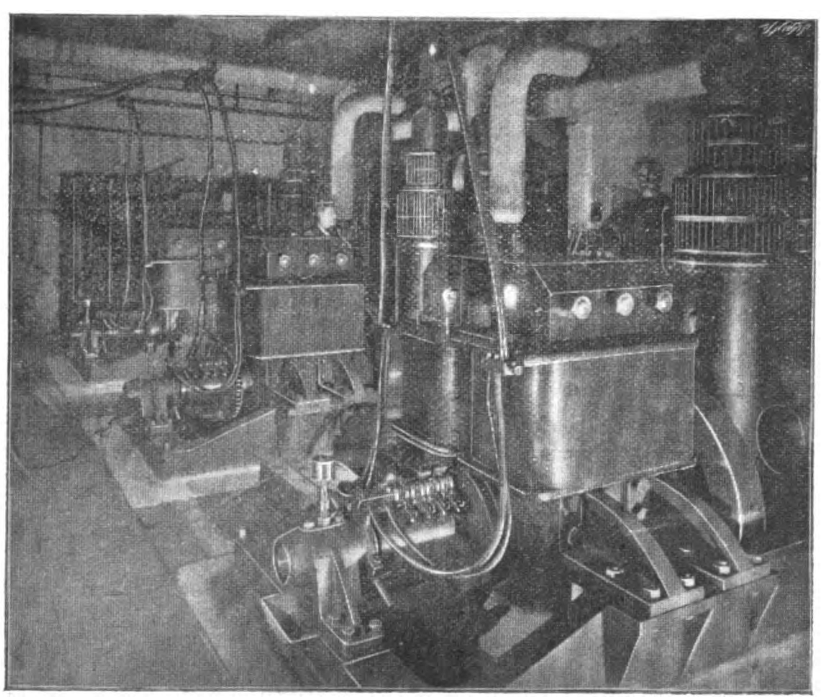
THE FOYER AT THE PALACE THEATER.

As we have suggested, most theaters nowadays rely on the public service for lighting, notwithstanding that some of them have to this day plant lying idle in their basements. Whatever reasons such places may have had for abandoning their private supply it is plain that they have not yet operated at the Palace Theater of Varieties, where a most complete system of private lighting is still in vogue. Structurally and decoratively we suppose this theater is still the finest in London, and everything harmonizes; the entertainment, the music and the lighting are among the remarkable features of what has been termed the most luxurious and the most comfortable building in Europe. So great is the confidence of the management in electricity that gas has been completely banished and there is not a single gas jet in the house; even the spirit lamps formerly employed at the bars for heating purposes have been replaced by electrical heaters.

We have recently made a detailed examination of the whole of the lighting plant that is employed here, and our experience is worth repeating. To start in logical order, it is necessary to make a descent—somewhat perilous to anybody but a sailor—

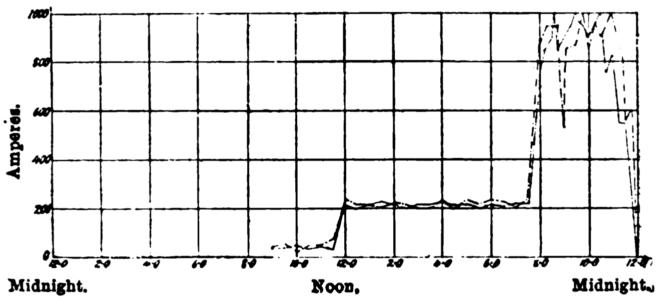
*From the *Electrical Review*, London.

to the engine and boiler rooms, which are some 24 feet below the level of the pavement. Here are installed, in a space that suggests some ingenuity in arrangement, three Marshall semi-portable locomotive boilers, which, at a steam pressure of 150 lbs., develop 80 horse-power. How to clean these boilers had been apparently a problem, for the back comes within 3 feet of the wall. Mr. W. Slade Olver, the chief engineer, surmounted the trouble in a somewhat ingenious manner, by having square holes cut in the wall immediately in the rear of the boilers, which gave access to a cellar, and the space thus provided enabled the stokers to operate their cleaning rods. There are not all the refinements in connection with the steam raising plant that one is accustomed to in central stations, and they would be obviously out of place; for instance, hand firing is considered good enough. There are, however, two Berryman feed-water heaters and vertical steam pumps made by the Deanes. Owing to the height of the building, the chimney shaft does not project more than 8 ft. above the roof, and, as a matter of fact, can be scarcely noticed at all. It is a point of some interest to observe that the water supply is obtained from sunk wells. The engine room is divided from the boilers by a party wall, and here are erected three Willans-Siemens sets. We have endeavored to give an idea of the engine room by means of photography, but, owing to the almost entire absence of daylight, artificial illumination had to be resorted to, hence the machines lack the distinctness that one usually obtains in central stations. The engines are of the single-acting central valve H H type, and the dynamos are of Siemens shunt-wound type, each giving 650 amperes at 110 volts. Beyond the paralleling switchboard, which is provided with the ordinary station voltmeter and ammeter, there is nothing more of importance in this room. The whole of the plant is, however, placed on a huge block of concrete, which is completely isolated from the side walls. Although such an arrangement of foundations has not in some places proved a bar to vibration, it is significant that at the Palace Theater no tremor whatever is observed in the interior of the building. On the roof faint pulsations can be observed occasionally, but then there is no one to complain of that. In any event, it would be a matter of extreme difficulty to communicate vibrations to surrounding property, for the theater itself is completely isolated from other buildings. In addition to the dynamos there is a battery of accumulators, consisting of 56 Epstein cells. The two halves of these are charged in parallel, four cells being utilized for hospital purposes. A battery regulating board is provided, furnished with the necessary devices.



ENGINE ROOM AT THE PALACE THEATER.

The mains from the engine room switchboard are carried to three main boards, two of which control the lighting in the auditorium, passages, stairs, vestibule, etc., and the third board controls the whole of the stage lighting. There are, therefore, three main circuits, called, respectively, A, B and C, the



TWO TYPICAL LOAD CURVES.

former one representing the stage circuits, the other two the front of the house. In accordance with the County Council regulation, the entrance and exit lights are arranged alternately on B and C circuits, so that in case of one circuit failing every other light would be still on.

In a sense the stage lighting is of the most importance, in so far as effects are concerned, and its proper regulation necessitates a somewhat elaborate board. Some alterations of the switching arrangements are in progress, and when completed the board will be probably one of the finest stage boards in London. The whole of the switching mechanism is placed at the right-hand side of the stage, at some distance from the ground, and from a special platform the footlights and the stage are controlled. The idea of the alternate circuits is carried out in the whole of the stage lighting. There are three sets of footlights arranged on alternate circuits, and the batten lights are connected in a similar manner. The lowering or dimming of the lights is a very important feature in the economy of stage management, and the alterations which are in progress include a set of liquid resistances. Up to the present, long lengths of platinoid wire have been utilized to give the necessary resistances, but these are now being done away with. The new scheme provides for a combined arrangement for dimming the entire front of the house; moreover, a new main break switch will put on circuits for stage effects, and it will be possible to produce sudden darkness in the house and stage together by interlocking through a bar any of the switches it is desired to operate. The ancient lime-light has been replaced by projector arc lamps, of which eight are in use, gas, as we have observed, being wholly tabooed throughout the building.

There are 10 arc lamps in front of the building, and the interior lighting consists of some 3,600 incandescent lamps, which are practically equivalent to 4,000 8-CPS. There are a number of ventilating motors fixed at different parts of the building, thus permitting the nicest regulation of the temperature of the building. Steam heating is used throughout the building, a system of live steam radiators being employed as well as a bank of radiators heated by the exhaust steam from the engine, fresh air being drawn from the street and blown into the theater by means of a Blackman fan.

As we have mentioned, the theater is connected to the supply mains; the total demand, however, which the company will meet is 2,000 amperes, and this can be turned on by means of change over switches, the amount of current per switch being 300 amperes.

It is hardly necessary to observe that electrical stage effects at the Palace are frequent. At the present moment there is the Biograph, which bids fair to rival Tennyson's brook, and there have been the wonderful series of living pictures, and latterly Zaeo and her electrical effects. As an indication of the demand for current that occasionally arises, it may be mentioned that one turn has required as much as 1,550 amperes.

A load curve cannot fail to be interesting, and some details as to cost will be useful. In 1897 the number of units generated was 234,798, coal and other fuel cost .59d., oil, waste, stores, etc., .11d., and wages .613., the total works' cost being 1.313d.

Electric Traction on Railways.

Improvements in train service, says P. Lanino in *Elettricità*, Milan, take the form of greater speed and more commodious carriages, the latter necessitating greater weight. Both of these require a more powerful locomotive; but, as the permanent way limits the size and weight of the locomotive, improvement ultimately consists in reduction of weight of the motor per HP.

The author considers that for steam locomotives the limit has now been reached, the best types developing 1,800 HP. and weighing 154 lbs. per HP. For progress, therefore, he looks to the electric motor fed from a central station, this being the lightest motor known; he believes that the weight can be reduced to 22 lbs. per HP., and that the absence of any reciprocating parts removes all limit to the ultimate speed attainable.

He describes the scheme of Davis and Williamson for an electric railway between New York and Philadelphia, to run at a speed of 187 miles per hour, and of Behr for a permanent way consisting of 5 rails supported on inverted V trestles. The latter, when tried at the Brussels Exhibition of last year, failed on account of the instability of the trestles.

Criticising the Heilmann locomotive, the author expresses his opinion that this will never prove superior to the ordinary steam one, as the great disadvantage of extra weight (220 lbs. per HP.) will outweigh the advantages of independent driving of each axle, triple expansion engines and greater regularity in the working of the engines. He believes that the present field of electric traction is that of local lines requiring frequent journeys and light trains, and cites as a successful example a three-mile trolley line opened at Baltimore in 1895. The locomotives weigh 90 tons, and have motors of a total power of 1,600 HP. distributed on six independent driving axles. The works' costs per ton mile, when 1, 2 or 3 locomotives are running, are, respectively, 0.186, 0.123 and 0.1015 pence. [The above is taken from *Science Abstracts*, London.]

THE ECKMÜHL LIGHTHOUSE.

France would seem to have been the first country to fully appreciate the advantages of electricity as a lighthouse illuminant. Until within the last ten or twelve years, mineral oil was used almost exclusively for lighthouse lamps, electricity previous to that time not being thought well adapted to this form of illumination, principally owing to a latent fear that through some accident to the generating machinery a lamp might become extinguished, which, as may readily be inferred, would have been a very serious matter. Another weighty reason which undoubtedly had considerable influence in causing the retention of oil lamps was the cost. When steam and electrical machinery are employed, skilled labor and frequent inspections are necessary, which materially adds to the operating expenses. As, however, electrical machinery was gradually improved upon, higher efficiency obtained and the cost of producing electric current proportionately reduced, according to a well thought-out plan France began the construction of a number of electric lighthouses along its coast, of which that of Eckmühl, embodying all the latest improvements, is the most recent and by far the most powerful. This new lighthouse, as may be seen by Fig. 1, is situated about one hundred yards back of the old lighthouse on a portion of the rocky shore of the Gulf de Moine in Brittany known as Penmarch Point. Work on this structure was begun in the fall of 1893, the expense of its construction being partly defrayed by a legacy of $60,000 to the French Government for this purpose by the Marquise de Bloqueville in memory of her father, Marshal Davout, Prince of Eckmühl. Thus does the lighthouse derive its name.

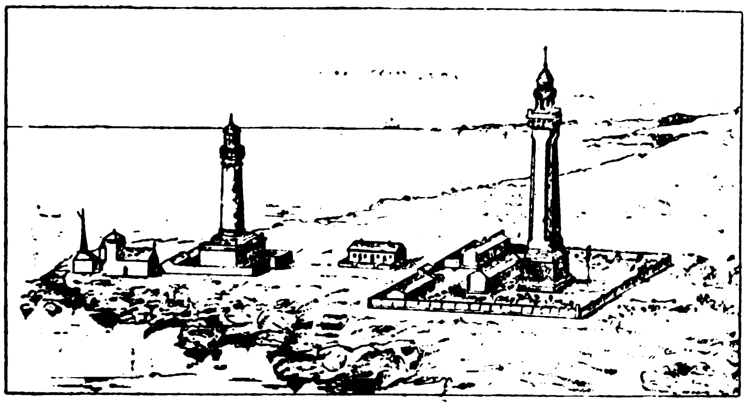


FIG. 1.

As is usual in France in the construction of most public works, special pains have been taken to give the lighthouse an attractive appearance from an architectural point of view, without however in any way detracting from its solidity or the purpose for which it was erected, and how well this has been accomplished may be gathered in a general way from Fig. 2. As may be seen by the illustration, a spiral stairway having 272 steps winds up in the interior. The total height of the tower above the ground is 206 feet, the plane of the light being about 209 feet 4 inches above high tide. At the foot of the tower and within an enclosure are situated several tastefully designed buildings containing steam boilers, engines, electrical machinery and other apparatus necessary in the operation of the lighthouse. The general arrangement of the engine and dynamo room may be seen in Fig. 3. The requisite amount of power for operating the fog-horn and lamps is obtained by means of two 12 HP. condensing engines. The latter are connected by means of belting to an overhead shaft which extends the whole length of the building. By means of this shaft the air compressor and alternators may all be driven at once, or if so desired the air compressor may be disconnected as well as one of the alternators, of which there are two. The latter generate two-phase currents which have been found to have several advantages over the ordinary alternating current for lighthouse use, notably in an increase in the steadiness of the light. It has moreover been found that by the use of dynamos generating two-phase currents, when the current of one lamp is for any reason cut off, the current passing to the other lamp does not increase more than one ampere in 25, whereas were the ordinary alternating current made use of this increase would be far greater. This peculiarity of two phase currents enables in the case of the Eckmühl lights of the carbons of one lamp being changed without extinguishing or causing the intensity of light in the second lamp to vary perceptibly.

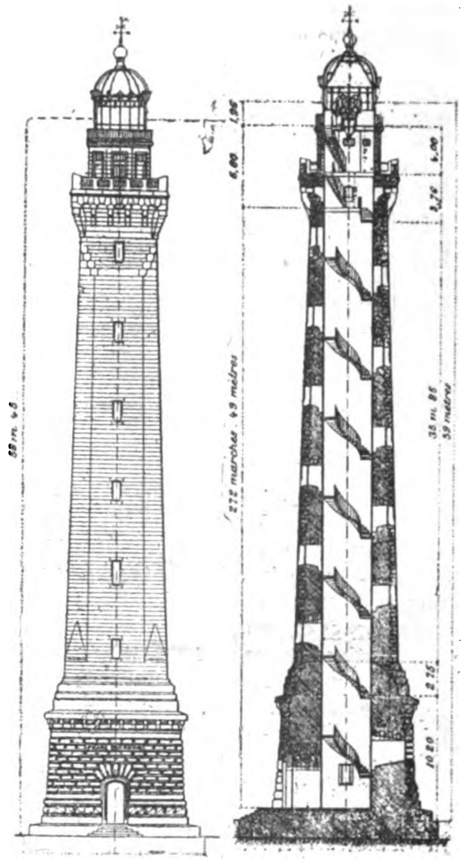

FIG. 2.

The alternators, as may be seen by Fig. 4, have eight poles, the intensity of their magnetic field being in the neighborhood of 4,000 C. G. S. units. Each is separately excited by means of a small direct-current machine fastened to the shaft as shown in the figure. The armature makes in the neighborhood of 810 revolutions a minute, and the resistance of each winding on the armature is .213 ohm. From tests that have been made it was found that the efficiency of these alternators varies between 70 and 75 per cent., depending on the speed at which they are driven.

The currents generated are of 25 and 50 amperes at a pressure of 45 volts. The air compressor, which is also driven by means of a belt from the main shaft, can be made to compress air to either four or fifteen atmospheres as desired. This compressed air passes to a small reservoir situated directly below the gallery on the upper part of the tower, where it is made use of during foggy weather for operating the sirene. The latter, located on the outside gallery of the tower, emits sounds of two similar tones (mi3) lasting three seconds and separated by an interval of similar duration, changing every ninety seconds to a uniform sound of the same tone also lasting three seconds. These sounds can be heard in clear weather from 7 to 8 miles. During time of heavy fog, however, the carrying capacity of the fog-horn is materially reduced, not exceeding under certain atmospheric conditions two miles.

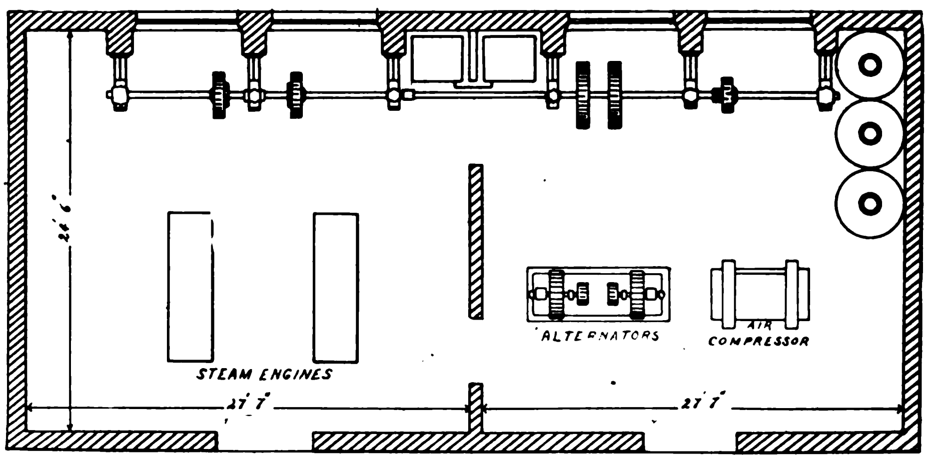

FIG. 3.

It is the lighting apparatus, however, wherein the Eckmühl lighthouse differs materially from any that has yet been built. This lighting apparatus, which is fifteen feet in diameter and almost twenty feet in height, is double; that is, there are two separate and distinct lanterns mounted one on each side of a common vertical shaft. An idea of the arrangement may be gathered by a glance at the cross section of the tower shown in Fig. 2. This novel arrangement was adopted at Eckmühl after careful investigation, as it was found that a far more powerful ray of light could be obtained with double lantern with less expenditure of energy, than in any other way. Each optical apparatus has four panels or windows composed of rims of prismatic glass so arranged as to disperse the light equally at all points in right lines; technically speaking, there are six dioptric elements and ten catadioptric elements. The whole illuminating apparatus, weighing over 4,000 lbs., is mounted upon a solid platform which is in turn connected to the vertical shaft previously referred to, being held upright by means of a circular drum resting in a trough of mercury. By this arrangement when the lights are revolved the frictional resistance is reduced to a minimum. The latter operation is accomplished in the way now in vogue in nearly all modern lighthouses, by means of a clockwork mechanism actuated by weights. It takes the Eckmühl lights twenty seconds to make one complete revolution, the flashes appearing every five seconds and lasting, as in all lighthouses along

the coasts of France, one tenth of a second. The reflection of these flashes may be seen, so it is claimed, under suitable atmospheric conditions, a distance of seventy miles. Carbons of 10 and 16 mm. diameter may be used in the lamps, which are both kept lit together. The intensity of the flash is regulated according to the condition of the atmosphere prevailing. On a very clear night, for instance, the 10 mm. carbons would be made use of, with but one alternator delivering 25 amperes of current at 45 volts to the lamps, whereas during heavy weather both alternators would be run, supplying 50 amperes of current at 45 volts to the 16 mm. carbons. The total number of hours a year during which the lamps have to be kept lighted is about 4 500, and during that period in the neighborhood 237,600 lbs. of carbon is consumed.

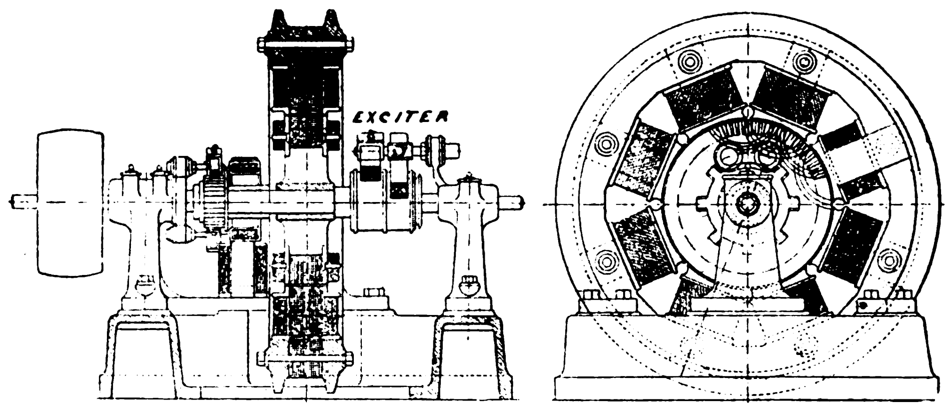

Fig. 4.

The illuminating power of the Eckmühl light is very great, greater in fact than any other lighthouse lamp in the world, with the possible exception of a light in this country designed by Mr. Henry Lapaute. Careful tests made with the Eckmühl lighting apparatus before it was permanently installed at Penmarch showed, at a distance of 650 yards, with 16 mm. carbons fed by a current of 50 amperes at a pressure of 45 volts, an intensity of light equivalent to 40,000,000 candle power. Besides the lights just described, two 12,000 candle power petroleum lamps are held in reserve to be used in the event of an accident happening to any part of the regular operating machinery.

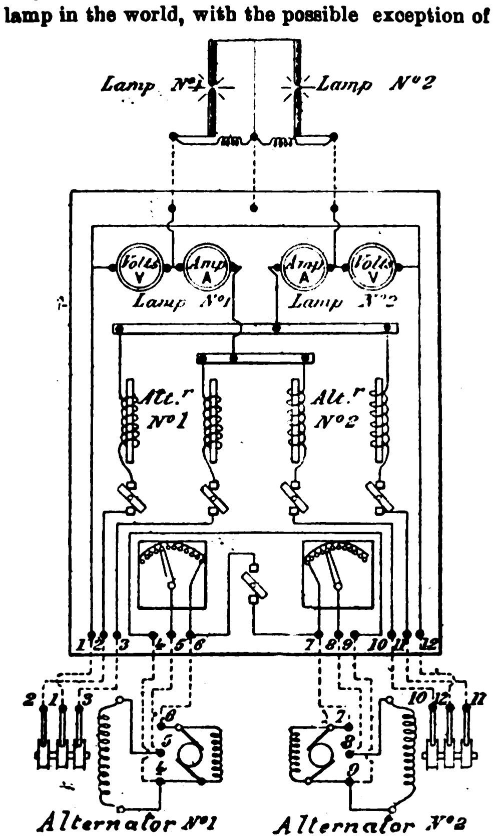

Fig. 5.

An excellent idea may be gotten of the general electrical installation at Eckmühl by an examination of Fig. 5. As will be seen, both a voltmeter and ammeter are placed in the circuit of each lamp, thus enabling the amount of current passing to either lamp to be determined at a glance.

The yearly operating expenses at Eckmühl are not nearly so great as might be expected, and far less than a similar lighthouse in this country could be kept in operation for the year round. Six men are constantly employed looking after the apparatus, whose salaries, with fuel and incidentals, make the yearly charges about $5,000. The total cost of erecting the lighthouse, as may already have been inferred, exceeded the legacy of $60,000 left for the purpose, the tower, buildings, machinery and optical apparatus having cost not less than $116,000.

[The above article, compiled principally from French sources, was specially prepared for ELECTRICITY. We are indebted to *L'Eclairage Electrique* for the illustrations.—ED.]

DIESEL'S RATIONAL HEAT MOTOR.*

BY E. D. MEIER.

All power which man uses, and all forces which he tries to curb and turn to his own purposes, have their origin in heat. Whether we spread the sails of a clipper to a spanking breeze, or urge an ocean greyhound at nearly railroad speed across the Atlantic ferry; whether we propel cars in the streets of Buffalo with electric force generated by the Niagara Cataract, or carry heavy packs on the backs of horses over frozen Klondike trails, we are using in some form the energy poured forth in lavish profusion by the central orb of our system. His heat causes the air currents which waft the ships to our shores; ages ago his rays called forth primeval forests, whose charred and compressed remains are fired under our steam boilers; vapors raised by his power from the waves of the ocean fall in life-giving rains on our continent, alike raising the level of the Great Lakes, whose waters feed the mighty cataract, and, in cooperation with his direct heat, calling forth bloom and fruit on the fertile fields whence man and brute nature alike derive their sustenance. Man, rising above the animal in his appreciation of the blessing of labor, first applied muscular force, and next what we are wont to designate as the natural forces, to assist him in his restless activity of production. Oars, levers, treadmills and all manner of harness for horse and steer preceded the use of wind or of falling water.

For centuries wind and water power were sufficient to drive all his machinery. The expansive force of steam, discovered by the ancient Egyptian, served but for a few simple actions, purposely enveloped in mystery to strengthen the superstition which priestcraft considered necessary for its schemes of government.

Even war, the delight, the pastime and the sole means of support of kings and nobles through many centuries, was slow in finding its most powerful agent in the explosive force of suddenly liberated heat. Finally, it was late in the seventeenth century that attempts were first made to utilize the expansive force of steam or of gunpowder in pumping water and for other useful purposes. And then, after the first experiments had demonstrated the tremendous force contained in these agents, these phenomena for a full century were of interest only to philosophers; and when Watt finally succeeded in harnessing the power of steam and making it work his will, inventors were already busy with engines designed to produce motive power by the explosion of gas or vapors.

Through all these centuries the forces employed were recognized by their effects, and no one suspected that the primal cause of all was the power of heat. Or, if we see in the early worship of the sun as the great life-giver some dim appreciation of this great physical fact, it had never yet risen to the height of faith or knowledge, nor had any one dared to attempt to measure and weigh heat in units of force.

The first heat motor which became a practical success—the steam engine—was for many years developed simply by gradual improvement of its mechanical appliances without any appreciation of the fact that heat economy was the primal consideration. It was, perhaps, well that this was so. Had the early inventors and designers of steam engines understood the limitations to which the steam engine is subject they would hardly have attempted to develop a machine which, after 100 years of experiment and another century of practice by the master minds of each generation, returns in work less than one-seventh of the potential energy residing in the fuel with which it is fed. And had they turned their attention to machines aiming at more direct transmutation of heat into work, the mechanical difficulties which would have confronted them might have retarded the industrial progress of the world by a full century; for, with all its defects as a vehicle of heat energy, steam has at least the one advantage that it can be used at very low pressures. The early engines gave results which for the time were of sufficient and even great value with pressures of less than 10 pounds to the square inch. Materials for higher pressures and temperatures were not available. These materials themselves had to be produced in larger variety and of better quality so that gradual increase in the pressure carried should give us as gradual an increase in fuel economy.

If the early inventors of internal-combustion motors were proceeding on more rational lines, so far as the final outcome was concerned they were kept back, and in many instances their efforts were foiled altogether by physical difficulties which required greater knowledge of metallurgy and greater mechanical skill than the world then possessed. For a full century the steam engine dominated the whole industrial field, and until twenty years ago it stood without a rival.

To an American engineer, Benj. Thompson, also known as Count Rumford, the world owes the first attempt to find an equivalent of heat in work, and the discovery that heat is not matter, but a form of energy. This important fact was communicated by Thompson, then residing in Munich, Bavaria, to the British Association for the Advancement of Science, just 100 years ago. Other experimenters followed, but it was not until much later that Joule, in England, and Mayer, in Germany, determined and fixed the mechanical equivalent of heat. Early in this century, Sadi Carnot, in France, developed the theory of a perfect heat engine, yet it was a long time before the clear reasoning of these men, though enthusiastically received and elaborated by Rankine, Zeuner, our own Thurston and others, found its way into the designing room of engine builders. For a long time the steam engine was studied only in its mechanical aspects, and the striking success of Corliss, while a great stride toward mechanical per-

*From the Journal of the Franklin Institute for October.

fection, tended rather to retard than to accelerate the study of the steam engine as a heat engine. It is still within the memory of most practising engineers of to-day that Hirn, by his wonderful series of experiments at Mulhouse, and his beautiful analysis of the results, aroused mechanical engineers to the importance of considering the utilization and conservation of heat in the steam engine as the fundamental question of design.

Naturally enough, then, when steam was once recognized, not as the cause but merely as the vehicle of the energy to be transformed into mechanical work, interest was revived in other heat motors. The experimental work of the beginning of the century was looked up, and the means and methods of the earlier inventors of engines, employing gas or oil vapors, were examined by many scientific and skillful engineers, who believed that there must be a more direct way of converting heat into work than the one through furnaces, boilers, and a long line of steam piping to the cylinder, where the conversion takes place.

Isherwood's conclusive experiment in regard to the waste resulting from the physical properties of steam had their due influence. Higher temperatures were sought, resulting in higher pressures, reheating and in increasing the number of cylinders. From the 4 to 8 pounds pressure of the earlier days, which could be contained in wooden boilers, such as some of you may remember to have seen in the water works in the city of Philadelphia, we have advanced to the 200 pounds and more carried by the great marine boilers of our ocean greyhounds and cruisers, and engineering schools possess experimental engines intended to determine the practicability of going up to 300 and even 500 pounds to the square inch. The vast industrial development brought about by the steam engine has given us metals, methods and data which enable us to contemplate such pressures with equanimity, and have developed lubricants capable of withstanding temperatures which ten years ago were prohibitory.

A little more than a year ago, Prof. Thurston published a scholarly discussion of the "Promise and Potency of High-Pressure Steam." His data were compiled from a number of careful tests on the triple and quadruple expansion engines of Sibley College, engines specially designed and admirably handled with a view of determining the possibilities and limits of progress in that direction. He concluded as follows:

"With equally excellent design, construction and management, we may expect the efficiency of the steam engine, with increasing pressures, to increase nearly as the logarithm of the boiler pressure.

"Gain in economy by increasing pressures simply must be expected to be slow and to steadily decrease in rate of gain as pressures rise, making the practicable, commercial limit a pressure comparatively low.

"The directions in which to seek for gain are the reduction of internal wastes and the production of a superheated steam engine."

According to this, if we can count in practice on 12 per cent. absolute efficiency with steam at 200 pounds, 14.2 per cent. would be the outside limit at 500 pounds, and 15.6 per cent. at 1,000 pounds steam pressures.

And in this reasoning the increasing difficulties of steam production and boiler economy at the higher pressures have not been considered. As he elsewhere finds cylinder condensation to account for from 18 to 34 per cent. of the total steam expended, the use of some more reliable vehicle for the heat than steam becomes imperative. Thurston's critical examination of the future prospects of the steam engine then points the way to the production and direct application of the heat at the very point where its energy is to be translated into work.

Thus, after an exhaustive analysis of experiments made with special steam engines of a higher and more developed type than are as yet to be found in practice, he arrives at definite conclusions which confirm and fix in exact limits the prophecies of men like Zeuner, Rankine and a host of others who have given eloquent testimony to the fact that the steam engine is wrong in principle. Thirty years ago Redtenbacher wrote to Zeuner that "the principle of steam generation and utilization is wrong; it is to be hoped that at a time not far distant the steam engine will disappear after we have acquired clear ideas on the nature and effects of heat."

All these utterances of men of genius naturally led to a renewal of interest in the internal combustion engine. Ericsson's brilliant failure in his attempt to substitute air for steam, and the final relegation of the hot-air engine to very small domestic pumping plants, seemed to put air out of the question as the vehicle for the heat.

The internal-combustion engine, experimentally developed by Barnett, in England, Drake, in America, and Lenoir, in France, improved by Brayton, Barsanti and others, and ably discussed and advocated by Dr. Siemens, became a practical motor in the hands of Otto in 1876. Otto's master patent, at first attacked as being but an adaptation of Beau de Rochas' theories, was sustained in the leading patent offices of the world, and became the foundation on which men like Priestman, Crossley, Atkinson, Capitaine, Clerk and others too numerous to mention, developed infinite varieties of type with a gradual and satisfactory increase in economy.

But they all worked in more or less beaten paths. The value of compression of the charge before explosion was recognized as increasing the initial pressure in the working cylinder. Means and methods for producing retarded combustion (the Nachbrennen of the Germans), or of slowing down the explosive action, were proposed and criticised with equal acumen and quite an expenditure of thermal units on the part of the disputants. Some of the mechanical devices evolved reflect the greatest credit on the skill and persistence of their inventors. But no one attempted a vital change in the cycle itself until Diesel appeared in the lists. Untrammeled by any previous experience in gas or oil engine construction, he was intent only on giving the clear and beautiful ideal of Carnot practicable and tangible form in a working engine. He experimented with various vapors more permanent than steam, until the very mishaps and difficulties encountered brought him face to face with the fact that the atmosphere about us could furnish a cheap, endless supply of a permanent gas, available not only as the vehicle of the heat, but as the means of evolving it from the fuel employed.

Rudolf Diesel is a Bavarian, forty years old. He received his early education in Paris, where his parents then resided, until they were forced to emigrate, in 1870, by the decree of the moribund Empire. He is a man of strictly temperate habits, a good mathematician and thoroughly versed in the science of thermo-dynamics, which he has made his life study. As a student at Munich he was a pupil of the celebrated Prof. Linde, now well known as the inventor and builder of the excellent ice machine which bears his name. Since the publication of his lecture of June 16, 1897, he has been fairly overwhelmed with praise and congratulations by the leading professionals of Europe. Perhaps no better gauge of the strong common sense and real greatness of the man can be found than the fact that all this praise and adulation has not turned his head in the least. He remains the same simple, earnest, conscientious student that he was before his great invention dazzled the experts in his line of engineering.

I was particularly struck with the simplicity, and I might almost say humility, with which he spoke of his great achievements. He considers his present success only as an incentive and a stepping stone to further work and progress. He is very accurate in all his statements, and thoroughly honest. Nothing can induce him to confound even his most sanguine hopes with a promise of any future success. He patiently and good-humoredly answered all my questions, and was instantly ready to show me authorities for his statements from the carefully chosen books of his extensive library.

As an engineer, he is more theoretical than practical, but has now at his command some of the best practical talent of Germany. Professionally well equipped and clear in his ideas, he is so simple and amiable in his manner that it is a pleasure to work with him, and these characteristics of the man promise to make the working together of the various interests in the many countries in which he has issued licenses satisfactory and beneficial to all, and will make a rapid progress in the practical development of the invention possible.

Mr. Diesel has been at work on the theories on which this motor works ever since he was a student at the Munich Polytechnic School. For the past fifteen years he has devoted himself almost entirely to this work. He even built a small experimental motor in Paris many years ago, the working of which enabled him to modify his first theories considerably. He, however, took the precaution to have the parts of this motor constructed in different shops to prevent his ideas and processes from becoming known. In 1892 he made his applications for his first patent in different countries.

In 1893, then residing in Berlin, he published a book on a new motor, which was translated in 1894 into English by Mr. Bryan Donkin, M. Inst. C. E., under the title "Theory and Construction of a Rational Heat Motor." In this little book Mr. Diesel developed an entirely new idea. It was this: To begin the work of combustion by first compressing atmospheric air to a point where its heat would become sufficient for ignition, and then gradually forcing into this compressed air a small quantity of pulverized fuel. This whole work was to be done in the cylinder of the motor, so that no heat would be brought into it from without. Mr. Diesel not only developed the theory, but suggested the leading principles of construction. At the time this book hardly went further than into the libraries and studies of men specially interested in the theory of thermo-dynamics. But Mr. Buz, of Augsburg, the general manager of the great machine works there, placed means and men at the disposal of Mr. Diesel to enable him to work out his theory in practice, and a 12 horse-power motor was built there on which many experiments were made. The improvements suggested were embodied in a second machine of the same size, and from this was evolved the 20 horse-power motor which established the working type now adopted. Mr. Fr. Krupp, of Essen, the German Steel King, also became interested in the matter. Mr. Diesel moved to Munich so as to be able to give his whole time to this work.

In the meantime, in 1895, a Mr. Schmidt, of Cassel, worked out and exhibited a steam engine working with highly superheated steam. For the time this motor attracted the attention of the engineering world; its defects were, however, so apparent that it did not come into general use, but it did serve to withdraw attention from Diesel and his work. On the 16th of June, 1897, Mr. Diesel delivered a lecture before the National Society of German Engineers at Cassel, in which he not only developed his theories, but exhibited in drawings the actual construction of his motor, and gave some data in regard to practical results obtained at Augsburg. Prof. M. Schroeter followed Diesel in further development of the theory of the motor, and gave in detail the results of tests made by him on the first experimental motor, and stated his conviction that the motor was now ready for commercial work. (These essays were published in the *Zeitschrift des Vereins Deutscher Ingenieure* of July 10th, 17th and 24th, 1897.)

At the conclusion of these papers a wave of en-

thusiasm swept over the large audience of professional engineers, and the desire naturally arose to see the motor at work. Mr. Diesel extended invitations to all engineers and manufacturers to visit the works at Augsburg and examine and test the motor for themselves. This invitation has been so generally accepted that for the next nine months the motor was practically on exhibit for every hour of the day, under the closest inspection by engineers, not only from Germany, but from every civilized country. It was therefore necessary to keep it running as a petroleum motor, and not until a month ago was it possible to dismantle the engine in order to make the slight but important changes necessary to adapt it to experimental work on gas.

Mr. Diesel's idea was to follow Carnot's cycle strictly, obtaining the lower isothermal and adiabatic curves by compression and the upper ones by combustion and expansion. For a long time he experimented with various vapors which, under normal conditions, are far above their point of condensation.

Ammonia vapors, especially, seem to have the properties best suited to the theoretical process. But great difficulties in handling them were encountered in practice. In the endeavor to replace them he was naturally led to experiment with air. Up to this time he had necessarily applied his heat from without and was subjected to the losses and limitations due to the metal walls through which it had to pass. He was then subject to the same losses which had defeated Ericsson, and was compelled to make the step which made his motor an internal-combustion engine. Starting out, then, with the intention of improving the caloric process of the steam engine, he reached, in a round-about way, means similar to those employed in gas and oil engines. But this similarity is strictly limited to the *fact* of internal combustion, the *method* of combustion being radically different. Further, finding that to begin his compression isothermally led him into pressures which must, in our present practice, be considered excessive, he abandoned that part of the Carnot cycle and made his compression adiabatic throughout, thus reducing the necessary pressures from over 100 atmospheres to between 30 and 40. When, as in the history of the steam engine, these higher pressures become practically feasible, a return to the original complete process may become advisable. Mr. Diesel's fundamental invention is then really a process for converting heat into work; this, of course, has been supplemented by other inventions naturally growing out of the persistent and logical development of a practical machine to operate on this process. I am happy to have available the description and opinion of no less an authority than Lord Kelvin, written by him after a careful investigation of Diesel's claims, and I will quote it in full.

"The invention may be defined as follows, (*a*) — (*h*):

"(*a*) Use a quantity of air very large in comparison with the quantity of fuel and which may be much larger than is required for complete combustion of the fuel. This air, at the beginning of (*b*) is at atmospheric temperature T; and is at a pressure somewhat above atmospheric pressure in virtue of the operation (*h*) described below, unless this operation is omitted.

"(*b*) Compress this air adibatically to a temperature far above that required to ignite the fuel under pressure.

"(*c*) Immediately after the dense air thus heated has commenced to expand, inject into it the fuel, whether gaseous or liquid, or finely powdered solid, thus causing the fuel to burn as it enters and to prevent, by the heat so generated, the expanding air from going down in temperature.

"(*d*) Regulate and distribute through a prescribed portion of the working stroke of the working piston the admission (c) of the fuel.

"(*e*) Use a governor to alter the duration and amount of the combustion (*c*) according to varying requirements of varying circumstances.

"(*f*) After the introduction of the fuel ceases, continue the expansion until the air is cooled sufficiently, nearly down to the atmospheric temperature (without any abstraction of heat by a water jacket). It becomes cooled to exactly the atmospheric temperature when it sinks to the atmospheric pressure, provided the concluding operation (*h*) of the cycle is properly adjusted, according to the extent of the operations (*b*) (*c*) (*d*) (*f*).

"(*g*) Reject the whole or part of this air from the machine, and take in fresh atmospheric air instead to make up the whole quantity with which we commenced in (*a*).

"(*h*) Keep now this air at atmospheric temperature by injected water, and compress it to such a pressure as shall cause the fulfillment of the condition stated at the end of paragraph (*f*). This operation may be advantageously omitted, with some sacrifice of theoretical thermo-dynamic economy, but probably with practical advantage, in smaller types of engine.

"If regulation (*d*) of operation (*c*) were so conducted as to keep the temperature at an absolutely constant degree (S) during the portion of the working stroke to which it refers, the series of five operations (*b*) (*c*) (*f*) (*g*) (*h*) would constitute an absolutely perfect Carnot cycle for the production of mechanical effect from a quantity of heat given at the temperature S, with T as the lowest temperature available for carrying off waste heat. The conditions, of course, cannot be *perfectly* realized in any real machine; but Diesel has shown how to make a good, practical approximation to their fulfillment, whether the fuel be gas, powdered solid or oil. He has already, with oil as fuel, realized this approximation with exceedingly good practical results, and has actually obtained 58 per cent. more work than any that has been given, from the same weight of oil, by any of the best oil motors previously made.

"The best economy of oil motors recorded in 'The Gas and Oil Engine,' by Clerk (Longmans & Co., 1896), is 371 grams of oil per BHP. hour, and the Augsburg tests of the Diesel engine give 234 grams of oil per BHP. hour.

"Besides this great advance in economy of fuel, Diesel's invention has given many collateral advantages of much practical importance. By supplying the fuel gradually to hot expanding air during a determined part of the working stroke of the main piston, and by using a much larger quantity of air than that required for complete combustion, he keeps the highest temperature reached by his engine several hundred degrees centigrade lower than the temperature essentially reached in the working cylinders of previous gas and oil engines. And the expansion after the end of the combustion gives a much lower temperature of exhaust without cooling by water jacket, than both expansion and water jacket together give in other gas and oil engines.

"Diesel's process of heating the air, simply by compression, to a temperature far above the igniting point of the fuel, before the fuel is introduced to it, supersedes all use of flame or hot chamber for ignition, even when the engine, cold in every part, is started for its first stroke by energy stored in a compressed air vessel from its previous working. This capability for instant starting from cold, and for stopping and starting again with perfect readiness at any time, is, I believe, a very valuable item of superiority, for many practical purposes, over any gas or oil or other interior-combustion engine previously made. Diesel's invention of introducing the fuel into air previously heated to far above the igniting point, merely by compression, and so causing the fuel to ignite, is, in my opinion, thoroughly original, and it has not been anticipated by any previous inventor. In nearly all previous gas and oil engines the air and fuel are compressed after being mixed together, with the great disadvantage that the degree of compression cannot go beyond comparatively narrow limits without causing explosion before the compression has ceased. In Barnett's third engine, the air and gas are compressed in separate pumps which, after the compression, discharge their contents into the motor cylinder. There they are ignited by means of a flame controlled by an igniting valve invented by Barnett (being almost identical in principle with the igniting arrangements used by many subsequent inventors). But neither Barnett nor any subsequent inventor anticipated Diesel in causing the fuel to be ignited by the high temperature produced by previous compression of the air into which it is introduced.

"Diesel is also quite original, and is, I believe, not anticipated by any previous inventor, in gradually introducing the fuel into expanding air, and so regulating and controlling the temperature produced by the combustion."

(*To be continued.*)

MODERN TRANSFORMERS.*

BY W. G. RHODES, M. SC.

One of the most important considerations in the construction and organization of an alternating current installation is the choice of suitable transformers. Upon such a choice depends to a great extent the efficiency of the whole plant and the regulation of pressure on the consumers' premises. If the light load losses in a transformer are not kept as low as possible, the all-day efficiency is seriously affected; if the secondary resistance is too high, and if there is appreciable magnetic leakage, the regulation may be so bad as to breed dissatisfaction amongst the consumers and consequent loss of custom. On this account it is not only advisable to have transformers possessing all the most modern improvements, but also to employ as few as possible consistent with the requirements of the area to be fed. It is, in fact, economical to replace large numbers of old type transformers by a few modern transformers having the same or greater aggregate capacity. This is well illustrated by the following cases:

In a town in Massachusetts having a population of 50,000, an alternating current station was constructed a few years ago, and 57 small transformers, having a total light capacity of 1,499 lights, were installed. Quite recently these have been replaced by 18 modern transformers capable of supplying 1,624 lights. The total core loss of the old transformers was 5,866 watts; that of the new, only 1,348. This difference in losses gives a yearly saving of 39,578 kilowatt-hours, which may be valued at about £132. Thus neglecting all the advantages except the diminution of core losses, the cost of the change will be met in 1 year and 9 months. The light capacity of the plant is increased 9 per cent., while the total core loss is decreased by 77.5 per cent. Further, on account of the decreased core loss, 4,518 additional watts are available for sale, producing an additional income of £169 at the present rate.

In another case 40 new type transformers replaced 53 old ones. The total capacity of the old ones was 1,135 lights, of the new 1,070. The core loss of the old transformers was 4,845 watts, and of the new 1,343 watts. This gives an annual saving of 30,678 kilowatt-hours, which will cover the expense of the change in 2 years and 9 months.

As regards regulation, we cannot too strongly urge the necessity of keeping it under full control. It is not necessary to point out how injurious to incandescent lamps is undue variation of voltage. If lamps are over-run, their life is considerably shortened, and frequent renewals are the inevitable consequence. This together with the bad light which results is bound to beget the distrust and disgust of the consumer. It is a fact frequently not realized

*From the *Electrical Review*, London.

that a change of 1 per cent. in the voltage causes a change of 7 per cent. in the candle-power of an incandescent lamp. A variation of 4 per cent. on either side of the normal voltage, that is a total variation of 8 per cent., means over 50 per cent. change in the candle-power. It is a lamentable fact that such changes are only too frequent in alternating current plants, and it is more than probable that this is the chief reason why so many alternating current stations fail to produce a dividend.

Why should this bad regulation occur? It is not because alternating currents are not as capable as direct currents of feeding any given area. It is because the management of alternating currents is not sufficiently well understood, and their application is not manipulated with sufficient skill. The phenomena of alternating currents are much more difficult to understand than those of direct currents, and no one is competent to undertake the management of an alternating supply station whose acquaintance with the subject is entirely of a practical nature.

I do not wish to depreciate practical experience, far from it, but I do wish to emphasize the necessity of sound theoretical training as well. A manager of an alternating supply station ought to understand thoroughly the cause of the bad regulation and to fully appreciate the various remedies. Bad regulation may be due to poor transformers, to large wattless currents caused by motors, etc., and to various other causes. Each cause has its remedy, and if the proper one is applied good regulation will result. Theoretical training enables us to determine the causes and their remedies; practical experience tells how best to apply the remedy.

I may safely say that the question of regulation is the most important of all to the supply company. What is more aggravating and annoying to the consumer than to have his 8 CP. lamps sometimes giving fully 12 CP., and at other times barely 3 or 4 CP., sometimes less than this? Yet such is the case with many alternating current stations. The result is, the consumers return to gas as being more reliable, the electric company loses its custom, or at any rate does not increase it. The electric supply committee grumbles because the plant does not pay, and the blame is laid on the alternating current. This is nonsense, sheer nonsense. The alternating current is all right if it is properly managed. It is the application and management which is at fault. The real reason why direct current are usually a greater financial success than alternating current stations is because the application and management is simpler and the regulation is more reliable. Make the regulation of an alternating plant equally good and the financial success will be greater, because often the losses in a direct current supply are greater than in an alternating current one. If potential wires are led from the centers of distribution to the generating station to give indications of the rise or fall of pressure, a competent man should be able to make an alternating current plant quite as reliable as is possible with continuous currents. Frequently it is an impossibility to attain the necessary high efficiency with continuous currents, and, having installed an alternating current plant, it is an admission of incompetency to allow it to be a failure.

An electric railway worked on the three-phase system will shortly be opened between Stansstad and Engelberg in Switzerland, so we are informed. The length of the line is about 11 miles, and part of it has a gradient of 25 per cent. on which the rack and pinion system will be used. The power will be derived from Obermatt, where a contemporary states a fall of 1,250 ft. will be utilized.

Now is the time to send in your subscriptions for "Electricity," the brightest, wittiest, best read, most widely quoted and popular paper in the trade.

SOCIETY NEWS.

Meeting of the American Institute of Electrical Engineers.

The 128th meeting of the Institute will be held at 12 West 31st street, New York City, this (Wednesday) evening, October 26, at 8 o'clock.

A paper will be presented by A. A. Knudson, of New York City, on "An Electrical Survey in the Borough of Manhattan, New York City," showing results of stray current measurements between electric railways, underground pipes, etc., also results of tests on the Brooklyn Bridge.

Applications have been received from the following candidates for associate membership which will be acted upon by council at its meeting November 23:

Howard Wallace Leitch, Brooklyn, N. Y.
John Cassidy, Honolulu, H. I.
C. Stowe Reno, Cincinnati, O.
James F. Cosgrove, Scranton, Pa.
James Wilkinson, Birmingham, Ala.
R. H. Sperling, Victoria, B. C.
James Hamilton, Boston Mass.
Bernard Hoffman, New York City.
Donald H. Fay, San Francisco, Cal.
S. L. G. Knox, Montclair, N. J.
A. Wilford Zohm, Minneapolis, Minn.
Cleveland Abbe, Washington, D. C.
Harvey D. James, Yonkers, N. Y.

A meeting of the Executive Committee will be held at 26 Cortlandt street, New York, this (Wednesday) afternoon at 4 o'clock.

Members who desire to present papers during the season are requested to communicate with Mr. Herbert Laws Webb, 15 Dey street, New York, chairman of the Committee on Papers and Meetings, or with the Secretary, Mr. Ralph W. Pope.

Meeting of the New York Electrical Society.

The 190th meeting of the New York Electrical Society will be held at the Pearl Street sub-station, Brooklyn, of the Edison Electric Illuminating Company of that city on Thursday, October 27, at 7:30 P. M. After an address on the company's work by Mr. W. S. Barstow, chief engineer, a brief inspection of the station will be made. The rest of the evening will be devoted to a flying visit to the sub-station "A" (formerly the Citizens' Station) and the big Union Central Station at Bay Ridge. Special parlor cars will be ready to take the visitors from the Pearl Street Station, and on the return trip from Bay Ridge a collation will be served on the trolley train.

In returning, for the convenience of the New York members, the Brooklyn Heights Railway Company has kindly arranged to run the parlor cars to the New York end of the Brooklyn Bridge.

Personal.

Mr. M. Cokeley, who is probably known to many of our readers, has been made superintendent of the works of the C. W. Hunt Company, Staten Island, N. Y., assuming the duties of that position October 14 after several months' work revising the factory system.

Large concerns are beginning to relieve the office management of the providing for the details in office routine, the installation of systems, methods, etc. This work properly belongs to a specialist, one who, constantly keeping his eyes open for improvement, studying the best literature on the subject and devoting his energy entirely to the work, becomes an expert. Mr. Cokeley has made this special work his profession for some time, being for many years with the General Electric Company and later with other prominent firms. His experience as a practical mechanic has been of great benefit in this line of work, enabling him to detect almost instantly the leaks that invariably exist and which are so destructive to profits.

CANADIAN NOTES.

The shareholders of the Montmorency Electric Power Company of Quebec have ratified the action of their directors in selling the property of the company to the Quebec, Montmorency & Charlevoix Railway Company. The shareholders of the former company not only receive for each $100 share of their stock in that company a share of an equal amount in the latter, but also a 20-year debenture of $100 bearing interest at 5 per cent. per annum.

The new Metropolitan Electric Company of Ottawa has purchased the Britannia water power at Britannia in the suburbs of Ottawa. The deal was completed last week, and the amount involved is said to be over $20,000. Mr. J. R. Booth, the millionaire lumberman, owned the water power, the capacity of which is estimated at about 40,000 horse-power, and he has given a guarantee to the Metropolitan Company that they could obtain 1,500 horse-power with an outlay of but $6,000.

The anchor ice trouble in the Ottawa river during the winter months will this season be overcome by the Ottawa Electric Railway Company by means of a large storage battery. The company has heretofore been troubled with anchor ice getting in the wheels at the power house. The power has been greatly lessened as a result, and occasionally the cars have been so short of power that they could not run. The new storage battery will act as an auxiliary and as a regulator.

Prof. V. L. Emerson's marvelous invention for the conversion of sawdust and sawmill refuse into commercial products was tested this week before a large gathering of the prominent lumbermen of the Ottawa district and of citizens, among whom were several members of the Dominion Government. Prof. Emerson says that the invention is a pre-eminent success. The machine gets its fuel from the gas obtained from the sawdust, so that the process is a continuous one. It runs automatically.

Annual Meeting of the Pennsylvania Street Railway Association.

The seventh annual meeting of the Pennsylvania Street Railway Association was held in the Board of Trade rooms at Scranton, Pa., on the 19th and 20th inst. Frank Silliman, Jr., general manager of the Scranton Railway Company, was chosen presiding officer in the absence of Robert F. Wright of Allentown. The proceedings were confined principally to an interchange of views.

Officers for the ensuing year were elected as follows: President, Frank Silliman, Jr.; first vice-president, William B. Given of Lancaster; second vice-president, Dallas Sanders of Girardville; secretary, S. P. Light of Lebanon; treasurer, W. H. Lanius of York.

Lancaster was selected for the next meeting.

On the evening of the 20th a banquet was given to the delegates by the Scranton Railway Company.

LEGAL NOTES

In the Hudson County (N. J.) Circuit Court on the 14th inst., Ida Schnaell and Louis Schnaell, her husband, of Union Hill, recovered a verdict of $15,000 damages against the North Hudson Railway Company. Mrs. Schnaell asserted that while alighting from one of the company's cars she was thrown to the street and severely injured by the sudden starting of the car. The jury gave her $10,000 and her husband $5,000 for the loss of her services.

A. L. Sailor and William M. Brown have been appointed receivers of the Braddock Electric Railway Company of Braddock, Pa. The receivers were asked for by Isaac M. Heidelberg and A. M. Sailor, officers of the company, and William M. Brown, an extensive bondholder. The bill states that the company is insolvent, the road not in operation and the equipment and assets are fast depreciating in value.

At San Francisco, Judge Seawell of the Superior Court has rendered an important decision dismissing

the application of the Board of Railroad Commissioners for a mandate to compel the Market Street Railway Company to produce its books for examination. The commission wished to fix a schedule of street car fares, but Judge Seawell holds that the term "railroad" in the statutes does not refer to street railways in the true meaning of the word, and that, although the commission is empowered to fix rates for carrying freight, the law does not imply the power to fix passenger rates, and that any other interpretation would involve the carrying of passengers and freight by coach and baggage companies. Judge Seawell holds that only municipal authorities have the power to fix the rates of street car lines. The case will be appealed to the Supreme Court.

THE NEWS.

What Is Going On In the Electrical World.

LIGHTING.

Auburn, N. Y.—It is said the D. M. Osborne Company is contemplating erecting an electric lighting plant to furnish light for its three big establishments in this city, and it is quite probable that the new plant will be constructed on a large enough scale to do a general lighting business.

Camden, N. J.—Proposals will be received at the city clerk's office until Wednesday evening, November 16, for lighting the streets of the city with arc and incandescent electric lights for the terms of one, three and five years, beginning July 1 next. Proposals should be marked "Electric Lighting" and addressed to Charles C. Southard, chairman.

Creede, Col.—This town has been in total darkness since the destruction of its electric light plant. It is proposed to build a larger plant and one that can furnish light all night.

Fostoria, O.—The City Heat & Light Company, besides purchasing the Fostoria Light & Power Company's plant and the lines of the Northwestern Ohio Natural Gas Company within the corporate limits, has purchased a well-located site for its power house and necessary buildings. All machinery will be of the latest and most improved types. The combined plants will cost $125,000.

Glencoe, Minn.—The local electric light company has been granted a ten-year franchise and has commenced work on the plant.

Grand Rapids, Mich.—The contract for the construction of the municipal lighting plant has finally been awarded to the Chase Construction Company of Chicago, concluding an agitation that has lasted about five years.

Harper's Ferry, W. Va.—The Harper's Ferry Light & Power Company has secured from the corporation board the right to establ sh an electric lighting plant here, and has been also given a contract to furnish arc and incandescent lights for town use.

Herkimer, N. Y.—The proposition to bond the village for $13,000 for the purpose of erecting an electric light plant was carried by a majority of 122 at the election held on the 14th inst.

Holly Beach, N. J.—The Seacoast Electric Light & Power Company's plant, which supplies the resorts of Wildwood and Holly Beach with light, has been sold at sheriff's sale to the mortgagee, Abraham Anderson, of Philadelphia, for $2,000.

Hutchinson, Minn.—H. A. Porter of Milwaukee is in this city to confer with a committee in regard to putting in an electric light plant.

Jonesville, Mich.—At a special election held here a few days ago to vote on bonding the town for $28,000 for electric lights and waterworks, the proposition was carried by a large majority.

Kokomo, Ind.—By order of the court the plant of the Citizens' Light & Power Company in this city will be sold at receiver's sale on November 12. The plant originally cost $70,000, and is the only commercial electric lighting plant in the city.

Lebanon, Pa.—Proposals will be received by the police committee of this city until November 7 for furnishing electric street lighting beginning June 1, 1899, to consist of 125 arc lights of 2,000 c.p. each. Proposals to be contingent upon a contract for five years, also for ten years, and price per lamp per year to be made accordingly.

Manheim, Pa.—In order to furnish the borough of Mt. Joy with electric lights, the Manheim Electric Light, Heat & Power Company will have to build a line across Rapho township from Manheim, a distance of seven miles. The company some time ago secured the franchise to furnish the light.

Malone, N. Y.—Superintendent of Banks F. D. Kilburn and S. F. Wright of Malone and J. H. Abbott of Gouverneur have made application to the board of trustees for permission to erect a new electric light plant here.

Miama, Fla.—It is understood that Mr. Flagler intends to establish an electric lighting system in this town at an early date.

Niles, Mich.—Considerable complaint is being made by citizens that the municipal electric light plant here is not self-sustaining, and it is becoming the general belief that the city made an injudicious investment or that gross mismanagement exists.

Schoolcraft, Mich.—Some time ago the proposition to bond the village for an electric lighting plant was voted down, but the subject is now being discussed anew and the council will before long be petitioned to call another election.

Somerville, Mass.—The aldermen have passed a resolution favoring the establishment of a municipal electric lighting plant by a vote of 6 to 2.

Wharton, Tex.—G. C. Gifford has purchased poles and machinery for the electric light plant and the work of construction will be begun at once.

Winchester, Va.—An incandescent electric light system is to be added to the arc light system now in use here. All the latest appliances in the way of electric machinery will be used, and it is expected that the new system will be in operation January 10 next.

Wooster, O.—The Wooster Electric Light Company has made a ten-year contract with the city to furnish eighty arc lights at $60 a light per annum.

STREET RAILWAYS.

Albany, N. Y.—The Board of Railroad Commissioners have authorized the Twenty-eighth and Twenty-ninth Street Cross-town Railway of New York City to change its motive power from horses to the underground system of electricity.

Cleveland, O.—Ordinances requiring the Cleveland Electric Railway Company to sell seven tickets for 25 cents on its Cedar avenue line and the Cleveland City Railway Company to make similar rates of fare on its Kinsman street line passed the city council on the 17th inst.

Columbus, O.—The Milford & Goshen Traction Company, incorporated here a few days ago, propose to run their road over the Wooster turnpike, paralleling the Little Miami Railroad as far as Milford, where it veers to the right. It will pass through Russells, Red Bank, Terrace Park, Plainville and several other towns. W. C. Compton, one of the incorporators, is the president of the Cincinnati, Columbus & Wooster Turnpike Company.

Detroit, Mich.—The "Tribune" states that on the 14th inst. C. H. Lawrence of the International Construction Company closed a contract for that company at Cincinnati to build an electric railway from Cincinnati to Hamilton, O., a distance of 25 miles, the contract price being $450,000. This line is independent of the Hamilton & Dayton line and has obtained consents over another route. When completed there will be two street car routes from Hamilton to Cincinnati.

Gallatin, Tenn.—A movement is on foot here to establish an electric car line from some nearby point on the Tennessee River to this city.

El Paso, Tex.—Capitalists at Fitchburg, Mass., have addressed parties here as to the probabilities of getting a franchise for an electric street railway in this city, and St. Louis men are also making investigations in the same direction, so that there is every likelihood that El Paso will have an up-to-date street railway before many months have passed. A franchise map showing the streets over which an electric line will be permitted to run has been drafted by a sub-committee of the citizens' general committee.

Montreal, Can.—An electric car of the Montreal Park & Island Railway Company which had been fitted with roller bearings was tested on the track a few days ago, and the system was pronounced very satisfactory by a number of railway men and experts who were present.

New Egypt, N. J.—Prominent citizens of this vicinity are talking of organizing a trolley company to run a line from Trenton via Allentown, New Egypt, Cassville and Lakewood to Point Pleasant. The places mentioned are only about eight or nine miles apart, covering a distance of about forty-five miles. Train service between this place and Trenton and Point Pleasant is very unsatisfactory, while there is no railroad at either Allentown or Cassville, both thriving villages.

New Rochelle, N. Y.—The "Pioneer" says: "The Huckleberry Electric Railroad officials announce that the new trolley road connecting the Pelham and Pelham Manor railroad stations and the double track connecting the old and new Boston Post Roads will be in operation by November 1. The company also expects to be running cars to the New Haven Railroad station at New Rochelle by the same time. So many promises have been made in New Rochelle by the trolley people that some of our citizens would not accept a statement under oath."

Niagara Falls, N. Y.—The Buffalo & Niagara Falls Electric Railroad Company has taken formal possession of the Buffalo, Kenmore & Tonawanda electric railroad, which it bought under foreclosure proceedings some time ago.

Pueblo, Col.—It is stated in the "Chieftain" that the Gold Belt line, at present about eight miles long, will be equipped with electricity as soon as the electric plant now building at Goldfield is completed, probably in February. Electricity on the road will entirely supplant steam as motive power. The total cost of the plant is $400,000.

Santiago de Cuba.—A franchise for an electric road from Santiago to El Caney has been granted by General Wood to prominent local business representatives. The road will be hailed as a boon by the people, but is hardly likely to pay more than expenses for a few years.

Stroudsburg, Pa.—Frank H. Smith, president of the Stroudsburg Passenger Railway, has applied to the council for permission to change the motive power of his road to electricity.

St. Louis.—The People's Railroad (cable) is to be sold under foreclosure proceedings to satisfy the claims of the third mortgage bondholders. The date of sale has not been fixed but it will probably be not later than the 1st of January. There is $800,000 in third mortgage bonds outstanding and the holders of these securities allege that the property has depreciated in value until it no longer is able to earn operating expenses, the value of the bonds being correspondingly depreciated.

Washington, D. C.—Charles J. Bell, appointed by the court trustee of the Belt Line Railway, has advertised the sale of the road to take place on November 15 next, at 2 o'clock. The sale will include all the rights and franchises of the company, together with its trackage, real estate, buildings and equipments. The terms of the sale provide that no one shall be allowed to become a bidder without having first made a deposit of $5,000. Within five days the successful bidder will be required to make a cash payment of not less than $62,000 or more than $75,000, which amount, it is estimated, will be necessary to meet the floating indebtedness, including the claims of the employes for wages and other bills recently decreed to be paid by order of the court. The company has 15 miles of single and 7½ miles of double track. The act of Congress passed at the last session requires that the purchaser shall equip the line with an underground electric system.

Westville, N. J.—The National Park Camp Meeting Association has decided to build a trolley line to Westville and Woodbury from the camp-meeting grounds.

Wilmington, Del.—Work is being pushed on the Wilmington & Brandywine Springs Electric Railway and it is intended to have its formal opening on November 1. Extensive improvements are under way at the Brandywine Springs Park.

Worcester, Mass.—The charter issued to the Worcester & Webster Street Railway Company authorizes the line to start near the city hall in Worcester, running through Auburn, Oxford and Webster to the postoffice in the latter town, about 15 miles. The capital is $150,000. The directors are Julius Garst, George A. Bigelow, E. L. Parker and F. P. Knowles of Worcester, E. S. Hill and H. S. Shaw of Webster, and L. E. Thayer of Oxford.

MANUFACTURING, ETC.

Chicago.—A. L. Kuehmsted, treasurer and general manager for the Charles E. Gregory Company in this city, is said to have just received an order for an electric light plant for North China. This plant, it is said, will be the first of the kind to be installed in that part of China. It consists of a 1,000-light dynamo, together with a complete equipment. It is considered by parties in the trade that this will be the beginning for quite a business in medium-sized plants from that part of the world.

Fort Wayne, Ind.—The Fort Wayne Electric Corporation is preparing to ship nine motors to London, Eng., in a few days. This is only one of the many foreign shipments the company has made this fall. It is stated that its dynamos, motors, meters and other apparatus are becoming quite popular abroad, and particularly with the English and Germans.

New York.—The "Journal of Commerce" in its export notes says: "Inquiries sent from Paris to electrical machinery manufacturers here strengthen the opinion that orders of some consideration are to arrive from that market early this winter. Two local manufacturing concerns are said to be figuring upon upwards of $200,000 worth of material required in various electrical undertakings in France. The orders that are at present arriving from France for this class of material are considered as being the best from any foreign market, not only for home consumption but for various foreign interests in which French capital is represented. Well posted parties say that for a period of more than six weeks the average weekly shipments of electrical material to Havre for distribution from there have amounted to nearly $10,000."

Oakland, Cal.—Superintendent Bishop of the Oakland Transit Company is quoted as saying that one of the great improvements contemplated by the company is the erection of an immense power house for the vast system of street railways now under its control, to be located on the water front. He says that it will be built on a scale never before attempted by any of the individual local companies. It will, moreover, be so designed as to admit of subsequent enlargements.

Pittsfield, Mass.—The "Journal" states that the Stanley Electric Company has secured through its San Francisco agency a contract for five transformers which are to be of an entirely new design and of the highest voltage of any machines of this kind that have ever been built. They are to be of 500 kilowatts or 675 horse power each, and are to be used on a transmission line extending from a distant point in the mountains to

San Francisco and other coast cities. The "Journal" says it is most probable that this order, which involves about $25,000, will be followed by others of a similar nature.

Washington, D. C.—United States Consul Prickitt writes to the State Department that the street railways at Rheims, France, which are now operated by horse power, are about to be changed to the electric trolley system, and suggests that contractors and furnishers of material for electric roads in the United States should compete for the contract. The railroads are operated by the Compagnie de Tramways de Reims, a Belgian company.

TRANSMISSION PLANTS.

Lowville, N. Y.—The Wetmore Electric Company expect to have their plant ready to supply electricity at the commencement of the new year. Work has been commenced on the transfer station on the Babcock farm east of this village. The stone building for the dynamo, water wheels and other machinery is already being constructed and poles are being strung from Belfort to Lowville.

Trenton, N. J.—The report is current that a company will soon be incorporated here to supply electric light, heat and power from a generating plant to be established at Morrisville. The rights of the Delaware River Improvement Company at that point are to be purchased and the water power improved so that at least 2,500 horse power will be available. Among the men reported to be taking part in the enterprise are John F. Dryden, president of the Prudential Insurance Company of Newark, N. J., Col. A. R. Kuser and Judge B. S. Woodruff of Trenton. It is said that besides putting up an extensive electric light and power works, the company proposes to purchase the rights of the Trenton Water Power Company, and negotiations to that effect have been begun with ex-Mayor Abram S. Hewitt of New York, the principal owner of the water power company.

COMPANY MATTERS.

Carthage, Mo.—The controlling interest held by Carthage people in the Southwest Missouri Electric Railway has been purchased by the Eastern owners for $336,200. The directory now includes four new Eastern men in place of the Carthage directors who retire. At the meeting of stockholders held on the 12th inst. at Carterville to confirm the sale the following directors were chosen: A. H. Rogers, president, Joplin; E. Z. Wallower, K. G. Neisley, H. L. Hershey, E. S. Herman, E. C. Felton, John E. Fox, W. J. Calder, Harrisburg, Pa.; Felton Bent, Philadelphia; J. F. Harrison, W. W. Calhoun, Carthage.

Johnstown, Pa.—A charter has been granted to the Johnstown & Somerset Traction Company, a corporation organized to build and operate a trolley line from this city to Windber, the new coal town of the Berwind-White Company in Somerset county. The board of directors is composed of Charles S. Price, Morris L. Woolf, David Barry, Herbert H. Weaver and Fred Krebs, all of Johnstown.

Toledo, O.—A deed has been filed in the recorder's office wherein the Toledo Electric Company transfers to the Toledo Traction Company all its franchise rights, privileges and property for a consideration of $375,000. The deed shows that the sale was consummated on October 11, but the transfer was really made about a year ago.

Troy, N. Y.—The "Record" states that "there has been a decided reconstruction of the Beacon Electric Company of Lansingburg and the company is now controlled by local stockholders. Samuel Bolton, Jr., has succeeded J. George Koebler as president, and Thomas Breslin of Waterford takes the place of vice-president left vacant by Mr. Bolton. Frank B. Twining has been elected a director in place of Albert Will of Rochester. The transfer of the majority of the stock to local holders had been for some time contemplated."

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—At a meeting of the Albany Institute Dr. William Hailes will read a paper on "Electrical Microscopic Projection."—Ever since the General Electric Company obtained possession of the Schenectady street railway it has been rumored that this company will extend its system from Schenectady to cities and towns in the Mohawk Valley and to Albany. Should this prove true, as many hope and believe, it is thought that most of the roads in Albany county would be operated by power obtained from the Mechanicville dam on the Hudson.

Cohoes, N. Y.—The conductor and engineer of the Delaware & Hudson train which struck the car of the Troy City Railway on Labor Day were arraigned for violating the city law in running at greater speed than eight miles an hour through the city. The defendants have entered a demurrer stating that the ordinance is invalid and void for several reasons which they state.

Schenectady, N. Y.—Lieutenant S. Dana Greene, former executive officer on the cruiser Yankee, gave an interesting address at the First Presbyterian Church October 20. The lecture attracted a large attendance. The subject of the lecture was the Navy and the experiences of the speaker as executive officer during the late war. His descriptions of the conditions in Cuban waters during the blockade were intensely interesting, especially in regard to the magnificent courage of the men who were detailed to cut the submarine cables. The speaker thought the behavior of these men had been too much slighted by the newspapers.

Hoosick Falls.—The electric railway from Hoosick Falls to Bennington is now running without the necessity of any transfers. The company's large iron bridge, which was displaced by the recent cloud-burst, is replaced by a trestle 150 feet long, over which the cars run. The electric company has given permission to the town officials to plank their iron bridge at North Hoosick, thus affording the public means to reach the village from the north with teams.

PERSONAL AND MISCELLANEA.

A baker at West Belleville, Ill., has put in electrical machinery to operate his bakery at an expense of $2,000. The plan has proved a success. The entire plant can be operated by one man and a boy and will turn out 9,000 loaves of bread in 24 hours without any danger of burning or suspicion of uncleanliness.

The Columbus, O., "Dispatch" states that Railroad Commissioner Kayler is calling the attention of municipalities to the practice of placing electric lights directly over the railroad tracks at street crossings. The presence of such a strong light is blinding to the engineer and defeats its purpose, often preventing the engineer from seeing persons on the tracks. The commissioner has been corresponding with mayors of cities in which such lights are located and has been meeting with satisfactory compliance.

A miniature electric searchlight for the use of policemen, watchmen, miners, engineers, etc., is on the market. It is a great improvement on the old oil-burning lamp. The new light is club shaped, made of leather with nickel trimmings, with a lens in one end that throws a brilliant light of considerable dimensions. Flashed in dark corners, in the rear of stores, in dark streets, it quickly reveals any person or thing. The light is of three and a half volts and the lamp in length is 8 or 9 inches and weighs about a pound. It is said to be good for several thousand flashes by simply pressing the thumb on a clasp. The illumination is furnished by a dry battery which may be replenished at a cost of 30 cents. The light complete costs $4.

William Henry Walsh of Albany, N. Y., has invented an ingenious system of automatic electric signals for railways which it is claimed will render impossible railway collisions and accidents from breaks or wrecks on the road. A representative of the "Weekly Press" of Albany, who witnessed the working of the system as shown by means of a miniature model, gives this description of it: "On a board, something over a yard square, was a system of brass rails, illustrating intersecting railways, or a crossing, over which the inventor runs a number of little engines equipped with his principle. In plain words the system may be thus explained: It is on the block, but not on the tower plan. Electricity is the agent and the signal box is in the cab of the engineer. Midway between the rails is another rail, a continuous and closely jointed metal rod. Connection is made with the engine or train by metallic brushes, or brooms, which sweep the rod. These brushes are connected with the battery in the engineer's cab. Each alternate block of the road is unwired. The instant the engine reaches a block, should there be ahead any breakage of rails, misplaced switch, part of a parted train, sinking of road bed, landslide, or anything else to cause a separation of rails, the bell rings in the engineer's cab and warning is given. Neither can a train enter a block while another is on the same block without the ringing of the alarm bell. The device is also designed to render impossible any accident by collision on crossings or intersecting roads. The reporter desired to ask questions and be allowed to cause an accident, both of which privileges were accorded him. Then he became a train wrecker for the nonce. He put obstacles on the tracks, misplaced switches, broke trains in twain and with devilish malice intent attempted to bring about head-on and tail-end collisions. He broke embankments, put rocks on the rails, spread them, undermined the road-bed; in short did everything fiendish in the way of causing a disaster, and each and every one of his felonious plans were prevented and frustrated by Mr. Walsh's wonderful invention."

RECENT COMPANY ELECTIONS.

Fairmount Park Transportation Company, Philadelphia, Pa.—President, Charles A. Porter; vice-president, Robert H. Foerderer, to fill the respective vacancies caused by the resignations of James Rawle and John W. Henderson. The directors of the company, additional to the elected officers, are: J. H. W. Chestnut, Frederick S. Dickson, Dr. L. F. Flibert and John B. Peddle, of New Jersey.

Electric Clock Company, Bangor, Me.—President and general manager, Joseph S. Smith; vice-president, Samuel R. Prentiss; superintendent, Walter J. Dudley; directors: Joseph S. Smith, John B. Foster, Charles V. Lord, Samuel R. Prentiss, Bangor; Arnold A. Rand, Philip A. Jenkins, Boston.

Meriden Electric Railroad Company, Meriden, Conn.—President, N. H. Heft; secretary and treasurer, W. L. Squire; directors: John L. Billard, John O. Byxbee, E. J. Doolittle, John M. Hall, N. H. Heft, John W. Mix and Charles L. Rockwell.

Nashua Street Railroad Company, Nashua, N. H.—Directors: John A. Fisher (president), August Fels, Percy Parker (treasurer), E. M. Tucke, F. C. Anderson, E. A. Smith and Miles F. Brennan. John P. Goggin was re-elected clerk.

Southbridge & Sturbridge Street Railway Company, Southbridge, Mass.—President, Calvin D. Paige; treasurer, F. L. Chapin; superintendent, Herbert H. Morse; directors: Calvin D. Paige, Francis L. Chapin, George W. Wells, Jacob Booth, Henry C. Cady, Albert H. Wheeler, Thomas S. Robinson, and Charles W. Hill and Chauncey M. Wells, auditors.

Toledo Traction Company, Toledo, O.—President, Albion E. Lang; vice-president and general manager, T. H. McLean; treasurer, W. E. Hale; secretary, Barton Smith; directors: the officers and N. B. Ream, J. E. Blair, John B. Dennis, Rufus H. Baker and W. H. McLellan.

Trenton Light & Power Company, Trenton, N. J.—Directors: James Moses, Richard A. Donnelly John Moses, G. D. W. Vroom, Alex. O. Yard, J. Ridgeway Fell, Charles T. Hughes and William B. Allen.

Worcester & Clinton Street Railway Company, Clinton, Mass.—President, A. S. Paton; vice-president, W. S Reed; clerk and treasurer, Walter R. Dame; directors: A. S. Paton, George R. Damon, W. S. Reed, George P. Damon, all of Leominster; James Marble and Col. T. S. Johnson, of Worcester; George A. Flagg, of Boylston, and Walter R. Dame, of Clinton.

Worcester & Webster Electric Railway Company, Worcester, Mass.—President, Julius Garst; vice-president, Fred Thayer; auditor, E. L. Parker; clerk, E. S. Hill; these officers and E. E. Carpenter, W. A. Bailey and H. F. Leland constitute the board of directors.

Yonkers Electric Railroad Company, Yonkers, N. Y.—Owing to the consolidation of the Yonkers Electric Railroad with the Union Railway Company, the officers of the Union road have been elected by the directors as officers of the Yonkers road. They are: Edward A. Maher, president; Albert J. Elias, vice-president; Thomas W. Olcott, secretary and treasurer. The change has brought about the retirement of M. F. H. Gouverneur from the position of general manager of the Yonkers road, that office having been abolished. Allan F. Edwards retains his position as superintendent of the Yonkers Division.

COMMERCIAL PARAGRAPHS.

The Montauk Multiphase Cable Co., 100 Broadway, New York, received the following note recently from the Milwaukee Auxiliary Fire Alarm Company:

Milwaukee, Wis., Oct. 1, 1898.

Montauk Multiphase Cable Co., New York.

GENTLEMEN: I am pleased to say that the Fire Department endorses and authorizes your cable for use in connection with our Auxiliary system here, Chief Foley telling me recently to "go ahead" with it. Superintendent Glassner of the Fire Alarm Telegraph has expressed himself as satisfied. Yours truly,

THOMAS R. MERCEIN,
Secretary and General Manager.

The name Packard is a synonym for everything that is progressive in the electrical line. It has always been the policy of the Packard Company to improve their material whenever opportunity offered. Their model '98 Packard Transformer represents their latest improvement in the transformer line. They claim to have a transformer which is at the very top notch of transformer construction. They have a novel plan of guaranteeing just exactly what each transformer will do. All of their claims, guarantees, etc., are fully set forth in a special circular, which can be had from the Electric Appliance Company, Chicago, Western agents for the Packard goods.

INCORPORATIONS.

The Electric Current Company, New York—to furnish electricity. Capital stock, $3,000.

The Northwestern Electric Heat & Power Company, Macon, Mo. Capital stock, $30,000. Incorporators: F. W. Blees, John F. Schafer and Charles E. Roehl.

The Illinois Traction Company, Chicago. Capital stock, $10,000. Incorporators: Augustus Kelly, Thomas S. Jackson and Clara L. Clayton.

The Hinsdale Light & Power Company, Lake City, Col.—to supply electric light and power to the mines. Capital stock, $100,000. Incorporators: R. E. Teniston, D. K. Anders and T. F. Ashworth.

The Standard Electric Construction Company, Rochester, N. Y.—to manufacture and deal in electrical apparatus. Capital stock, $5,000. Directors: Edgar H. Freeman, Walter H. Tobey, Burton A. Vandy, all of Rochester.

The Joplin Illuminating Company, Joplin, Mo. Capital stock, $80,000. Stockholders: John C. Porter, Harrison I. Drummond, Charles Nelson, John S. Dunham and Francis Kuhn.

The Milford & Goshen Street Railway Company, Cincinnati, O.—to build and operate an electric railway in Hamilton and Clermont counties, Ohio. Capital stock, $10,000. Incorporators: William A. Goodwin, M. C. Campton and others.

The Bay Ridge Electric Park & Steamboat Company, Baltimore, Md.—to conduct a pleasure resort and run a steamboat line. Capital stock, $50,000. Incorporators: Julius M. Jackson, Edward D. Crook, John R. K. Collins and Louis K. Meyer.

The Lake City Power Company, Denver, Col.—to furnish electric light and power in and around Lake City from a plant to be established at an available point on the Gunnison river. Capital stock, $50,000. Incorporators: David K. Lee, B. Gibson and Frank C. Gaudy.

The Insulated Wire Company, Jersey City, N. J.—to deal in insulated wire and other goods. Capital stock author-

ized, $500,000. Incorporators: Samuel B. Lawrence and John B. Summerfield, New York, and Burnham C. Stickney, Elizabeth, N. J.

The Pike's Peak Power Company, Council Bluffs, Ia., and Colorado Springs, Col.—to acquire the rights and privileges granted to George W. Jackson by the city of Colorado Springs, conferring the right to lay underground conduits and wire cables and to erect poles and string wires to furnish electric power. Capital stock, $100,000. Directors: Thomas A. Whelan, F. A. Chapman, Henry M. Blackmer and Van Lear Black. Chancellor L. W. Ross will represent the company in Iowa.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 18, 1898

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

12,410. Electric Trolley Device. Alfred J. Gairing, Johnstown, Pa., assignor to the Steel Motor Company, same place. Filed Aug. 3, 1898.

612,457. Electric Railway. Charles H. Myers, Buffalo, N. Y., assignor to himself and Percy Marvin, same place. Filed Aug. 18, 1897.

612,641. Depressible-Rail System for Electrical Railways. William Grunow, Jr., Bridgeport, Conn., assignor of one-half to Zalmon Goodsell, same place. Filed July 10, 1897.

612,696. Rail-Joint for Electric Railways. Max Barschall, Berlin, Germany. Filed March 14, 1898.

612,703. Automatic Electrically-Controlled Railway-Switch. Robert V. Cheatham, Louisville, Ky. Filed March 12, 1898.

612,785. Street-Car Fender. George A. Parmenter, Cambridge, Mass. Filed July 11, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

612,556. Electric-Arc Lamp. Charles A. Vigreux and Lucien V. Brillie, Levallois-Perret, France. Filed March 30, 1898.

612,560. Electric-Lamp Socket. John E. Origgal, Newark, N. J. Filed Nov. 4, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

612,629. Means for Controlling Operation of Electric Motors. John D. Ihlder, Yonkers, N. Y., assignor to the Otis Brothers & Company, New York City. Filed Jan. 26, 1898.

TELEPHONE AND TELEGRAPH APPARATUS.

612,681. Telephone-Exchange Mechanism. Harlen P. Snow, Erie, Pa., assignor of one-half to Frederick C. Jarecki, same place. Filed Nov. 1, 1897.

612,782. Coin-Actuated Signal Apparatus. Heber R. Mason, Ludington, Mich., assignor to the Mason Telephone Pay Station Company, same place. Filed Dec. 31, 1897.

SIGNALS AND SIGNALING APPARATUS.

612,708. Electric Signaling Apparatus. William E. Decrow, Boston, Mass., assignor to the Gamewell Fire Alarm Telegraph Company, New York City. Filed Dec. 27, 1897.

612,709. Electric Signaling Apparatus. William E. Decrow, Boston, Mass., assignor to the Gamewell Fire Alarm Telegraph Company, New York City. Filed Jan. 4, 1898.

MISCELLANEOUS.

612,426. Electric Meter. William D. Marks and George R. Green, Philadelphia, Pa., assignors to the American Electric Meter Company, same place. Filed Jan. 10, 1898.

612,427. Electric-Meter Case. William D. Marks, Philadelphia, Pa., assignor to the American Electric Meter Company, same place. Filed Jan. 10, 1898.

612,441. Electric Time Alarm. Herbert D. Tenny, Milford, Mich. Filed Feb. 19, 1898.

612,535. System for Insulation of Electric-Conductor Wires. Jonathan H. Vail, Philadelphia, Pa. Filed Feb. 26, 1898.

612,649. Battery-Electrode. Herbert S. Lloyd, Philadelphia, Pa. Filed Sept. 20, 1897.

612,670. Electric-Cable Switch. Addison Norman, Toronto, Canada, assignor of one-fourth to William McCabe, same place. Filed April 19, 1897. Renewed June 29, 1898.

612,694. Process of Simultaneously Producing Carbids and Metals or Alloys. Heinrich Ascherman, Cassel, Germany. Filed March 30, 1898.

612,781. Electric Meter or Indicator. William D. Marks, Philadelphia, Pa., assignor to the American Electric Meter Company, same place. Filed Feb. 7, 1898.

612,789. Electric Self-Loading Street-Cleaning Car. Andrew J. Reynolds, Worcester, Mass. Filed Feb. 2, 1897.

TELEPHONE AND TELEGRAPH.

The Telephone Dispute in Washington.

Comptroller of the Treasury R. J. Tracewell has rendered a decision relative to the controversy between the United States Government and the Chesapeake & Potomac Telephone Company which will probably hasten the action of the Supreme Court of the United States as to the constitutionality of the Act of Congress, passed June 30, 1898, fixing the price for telephone service in the District of Columbia at $50 per annum for the use of a single telephone instrument on a single wire. The Washington *Times* explains the circumstances which led to the Comptroller's decision: "In August, 1897, the Government Printing Office entered into a contract with this company [the Chesapeake & Potomac] to be furnished telephone service at the company's price. June 20, 1898, Congress passed a law fixing the amount which may be paid for the use of telephones in the District of Columbia. The Public Printer claims that this act of Congress invalidates the contract entered into by the Government Printing Office and the Chesapeake & Potomac Telephone Company. The telephone company disputed the law in this case and the matter was left to the decision of the Comptroller of the Treasury. Mr. Tracewell's ruling is that the telephone company must furnish both individuals and the Government the benefits of its telephone system, and do this under the rule of charges fixed by law, or give way to others who will."

The Syracuse, N. Y., *Herald* states that Frank L. Woods, receiver of the New York State Telephone Company, is the plaintiff in actions at law just begun against the Auburn Telephone & Service Company and the Oneida Telephone Company, sued jointly, and George McClumpha. The first action is to set aside the alleged illegal transfer of stock and property which it is claimed were conveyed to the defendant companies when the plaintiff's company was about to become insolvent. Fifteen thousand dollars is the alleged value of the stock and property. The same questions are involved in the suit against McClumpha.

A new telephone company has been organized at Wilkes-Barre, Pa., to be known as the People's Telephone Company of Wilkes-Barre, and with Samuel E. Wayland as manager has perfected arrangements to begin work at once in getting its lines ready for operation. The company has a State charter and franchise and proposes giving service through long distance telephones. The stock of the company is held by local capitalists, among them John W. Hollenback, George A. Bedford, W. A. Lathrop, Abram Nesbitt, Irving A. Stearns, C. F. Stegmaier and A. Markle.

The Home Telephone Company of Cleveland has applied to the Board of Control for official sanction of a formal transfer of its property in Cleveland to the Cuyahoga Telegraph & Telephone Company, which corporation, if the petition is granted, will operate the Home Company's lines in Cleveland.—The Union Suburban Telephone & Telegraph Company of Cleveland has been officially authorized to change its name to The United States Telephone Company.

At a meeting of the board of directors of the Western Union Telegraph Company in New York on the 19th, the old officers were all re-elected, with the exception that Thomas F. Clark, acting vice-president, was elected vice-president and was also elected director in place of J. W. Clendenin, deceased, and that M. T. Wilbur, assistant treasurer, was elected treasurer in place of R. H. Rochester, deceased.

Cleveland, O., is being extensively conduited at the present time. Four different companies are laying conduits for electric wires in various parts of the city. The companies are the Cleveland Telephone Company, the Home Telephone Company, the Postal Telegraph Company and the Cleveland Electric Illuminating Company.

The Union Extension Telephone Company has been organized at Union, S. C., with M. W. Bobo of Sedalia as president and general manager and Allan Nicholson of Union treasurer and manager of the Union end of the line. The company gives connection with Sedalia, Cross Keys, Enoree, Laurens, Abbeville, Anderson, Belton, all in South Carolina, and expects to soon connect with Spartanburg.

Colorado Springs capital has become interested in a new telephone line to be erected in Oklahoma, $20,000 having been subscribed for the construction. The new company will be known as the South McAllester Telephone Company.

A press dispatch from Reading, Pa., states that the city councils have struck from the calendar the ordinance giving the Pennsylvania Independent Telephone Company the privilege of the streets to start a telephone service for which it had secured over 300 subscribers.

The Drawbaugh Telephone Company.

The Drawbaugh Telephone Company of Philadelphia, which filed plans of its proposed system in that city with the Board of Highway Supervisors recently, has a capital stock of $2,000,000 and its purpose is to furnish a complete telephone service at the uniform annual rate of $75 for business places and $50 for residences. The plans filed show that the company intends to cover every part of the city of Philadelphia with its system, and one novelty, compared with the system made familiar to telephone users, will be that there will be no central station in the sense that one is now necessary. Each branch station will practically be a "central" for the subscribers in the district in which it is located. The officers and directors of the company are: President, Col. J. F. Stokes; secretary, Charles A. Gladding; treasurer, John D. Ford; directors: Albert Baltz, Henry Levis, Henry H. Hallowell, Edwin S. Cramp, Charles E. Hodges, J. F. Stokes, John D. Ford, Charles A. Gladding, William O. Hampstead, Herman A. Lang and Samuel F. Kent.

A press dispatch from Richmond, Ky., states that local capitalists are trying to buy up and consolidate the various telephone lines in Central and Eastern Kentucky. There are 25 lines, reaching nearly every county seat from Somerset on the south to Maysville on the north. It is estimated that it will take $100,000 to buy the various lines.

The People's Telephone Company at New Orleans has begun the construction of its conduits. William P. Curtis, the general manager of the new company, in speaking of the present and future plans of the enterprise, is very hopeful of its success, and predicts a new spirit of progressiveness as a result of the competition afforded.

The United States Supreme Court has declined to advance the case of the city of Richmond against the Southern Bell Telephone and Telegraph Company. It will not, therefore, be reached before March or April of next year.

A telephone line between Tacoma, Wash., and San Francisco, with branch lines to British Columbia and Mexico, has just been completed, making the longest telephone line in the United States.

A dispatch to the New York *Commercial* from Kansas City, Mo., states that the Standard Telephone Company has bought all the lines and equipment of the Central Missouri Telephone Company.

The Erie Telegraph & Telephone Company reports that it added 1,094 subscribers to its system during the month of September last. The total number connected October 1 was 28,771.

The long distance telephone line connecting Birmingham, Ala., with Nashville, Chattanooga, New York and other cities has been completed.

The telephone system at Sioux Rapids, Iowa, connecting that city with several surrounding towns, has been thrown open to the public.

New Companies Incorporated.

The Amherst Telephone Company, Amherst, Mass. Capital stock, $4,000.

The Citizens' Telephone Exchange, Peoria, Ill. Capital stock, $200,000. Incorporators: Deloss S. Brown, Hart F Farwell and John Skinner.

The People's Telephone & Telegraph Company, Worcester, Mass. Capital stock, $150,000. President, Israel L. Currier; treasurer, Fred W. White.

The People's Telephone Company, Lockport, Ill. Capital stock, $12,000. Incorporators: Allen G. Hawley, Charles B. Cheadle and Thomas Cheadle.

The Rivershore Telephone Company, Burlington, N. J.—to do a telephone and telegraph business. Capital stock, $15,000. Incorporators: Nathan Haines, J. Howard Pugh and George C. Gunn of Burlington; Mitchell B. Perkins, Beverly, N. J.; Henry V. Massey, Philadelphia.

The National Automatic Telephone Company, with principal office in Chicago, Ill., has been incorporated at Charleston, W. Va., by John Anderson, E. W. Ober, W. W. Watson, C. A. Watson, L. A. Will, F. A. Lundquist and J. D. Milliken. Authorized capital stock, $1,000,000.

The Oakland Messenger, Burglar & Fire Alarm Company, Oakland, Cal.—to erect, maintain and operate telegraph lines in Oakland for the purpose of transmitting burglar, fire, police, messenger and other signals and send and receive telegraph messages in the city. Capital stock, $20,000, of which $6,050 has been subscribed. Incorporators: Albert Anker of Tehachapi, Henry N. Beck and Frederick Kahn of Oakland, Philip Marx of Los Angeles and Edward I. Wolfe.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12.30@12.37½c.; Lake, 12½c.; casting, 12¼@12½c.

The United States took formal possession of Porto Rico October 18.

The Columbus (O.) Street Railway Company has declared a dividend of 1 per cent. on its capital stock, payable November 1.

The Consolidated Traction Company of Pittsburg, Pa., declared a dividend of $1.50 per share on its preferred stock, payable November 14.

The Henry Worthington Company has declared a semi annual dividend on the preferred stock of 3½ per cent., payable on and after November 1.

The Dry Dock, East Broadway & Battery Railroad Company, New York, declared a quarterly dividend of 1½ per cent., payable October 20. Transfer books reopen November 2.

The Nassau Electric Railroad Company, Brooklyn, has been fined $100 for using soft coal at its power house in South Brooklyn, the courts having decided that the burning of soft coal there constituted a nuisance.

The present earnings of the Baltimore Consolidated Traction Company are reported to be at the rate of 6 per cent. The company now pays 4 per cent. per annum, but the rate is to be made 5 per cent.

The directors of the Sprague Electric Company, New York, have declared a semi-annual dividend of 3 per cent. on the preferred stock, payable November 1. Transfer books will reopen November 2.

The Hudson River Telephone Company has declared a regular quarterly dividend of 1 per cent., payable November 1. The company is reported to have earned $100,000 net in nine months of the present year.

A $40,000 mortgage has been filed in the county clerk's office at Rochester, N. Y., by the Lima & Honeoye Falls Electric Light & Railroad Company in favor of the Buffalo Loan, Trust & Safe Deposit Company.

A distribution of $2 per share upon the common stock of the Street Railway & Illuminating Properties was declared payable at the office of the company in Boston on the 22d inst. to holders of record at the close of business on the 19th.

The Staten Island (N. Y.) Electric Railroad Company reports for the quarter ended September 30: Gross earnings, $76,736, increase over the same quarter in 1897, $14,528; operating expenses, $38,107, increase $8,830; net earnings, $38,629, increase $5,698.

The annual meeting of the Pennsylvania Heat, Light & Power Company took place at Philadelphia on the 19th inst. As all the stock is held in trust by the Guarantee Trust Company to secure the Electric gold 5s, proceedings were perfunctory, the old board being re-elected.

At a meeting of the shareholders of the Royal Electric Company, Montreal, on the 18th inst., it was voted to increase the company's holdings of Chambly Manufacturing Company's stock from $200,000 to $300,000. The proposal to issue $500,000 preference stock of the Royal Electric Company was turned down.

The District Commissioners, Washington, D. C., have issued an order approving the issuance by the Columbia Railroad Company of $500,000 worth of bonds, under the recent act of Congress authorizing the company to extend its road eastward to the District line, by way of Benning, Deadwood and Watts Creek.

The Milwaukee Railway & Light Company has about completed a tunnel under the river, which will be used for carrying all feed wires for the railway and light system to the west side of the river, including the power for the Wauwatosa and Waukesha lines. Power will be furnished direct from the new power plant of the company now being built.

The United Electric Securities Company, Boston, has declared its regular semi-annual dividend of $3.50 per share on the preferred stock; also a dividend of $3.50 on the same stock, being the dividend due August 1, 1896, which has been until now unpaid. Both these dividends are payable November 1 to stockholders of record October 25. Transfer books reopen November 2.

It is estimated by the committee of the proposed new independent telephone company at Worcester, Mass., that the enterprise can be started for $165,000. The committee is composed of Henry F. Harris, William H. Barnes, E. P. Curtis, William Hart and Frank O. Plummer. The committee state that there is no connection between the new company and the People's Telephone Company.

The United Electric Light & Power Company of New York, following the example of the Edison Electric Illuminating Company, has issued a circular and arranged a new schedule of rates for lighting, heating, cooking and power purposes, adopting the three-quarter-cent basis for a 16 CP. lamp per hour as against the one-cent basis of the Edison Company. The latter will, it is expected, meet the undercut.

In announcing a semi-annual dividend of 3 per cent., payable October 31, the Exeter (N. H.) Street Railway Company states that the road had been in operation fifteen months, and shows a net gain of $9,148.17. The line will be extended soon to connections with Newburyport and Amesbury on the south, and with Portsmouth on the north, making one of the best suburban railroads in the New England States.

An interest in the Philadelphia Electric Storage Battery management, according to a current item, says that the company has done over $1,000,000 worth of business in the nine months of the present year as compared with the gross sales for the full year of 1897 of $959,000. The same authority states that the chances are good that the company will do at least $1,500,000 this year, on which net earnings of $500,000 ought to be shown.

dispatch to the Indianapolis "News" from Terre Haute says the holders of first mortgage bonds of the Terre Haute Street Railway (Russell Harrison's road) "will next month ask the judge of the Superior Court for permission to foreclose on their bonds because of default in the payment of interest. It is believed the court will grant the request. The property is in the hands of a receiver. It had been the intention of the bondholders to foreclose this month, but for some reason the step will not be taken until next month."

The $2,000,000 first consolidated mortgage 4 per cents of the Edison Electric Illuminating Company of Brooklyn, offered recently at 93½ per cent., were over-subscribed. The union of the Edison Company and the Kings County Electric Light & Power Company has now been perfected, only about sixty shares of the Edison Company remaining unexchanged. The interest charges of the Edison Company, including the consolidated mortgage bonds now issued, will be $155,000 per annum. The net income for the calendar year 1897 of the Edison and Municipal companies applicable to charges was $487,000.

The Boston "News Bureau" of the 24th inst. states that the directors of the General Electric Company on that day declared a dividend of $7 per share upon the old preferred stock and $11 1-5 per share on the new preferred. The New York "News Bureau" of the same date says: "The General Electric Company has declared a payment of 11 per cent. in cash on its preferred stock, representing part of the accumulated back dividends." The two statements are conflicting and we must await the official announcement to set the matter straight. It must be welcome news, however, to the stockholders that General Electric has at last declared a dividend of any sort, and we feel assured that these gentlemen will now duly appreciate the efforts made in the columns of ELECTRICITY for several years past to bring the company to its senses.

ELECTRICITY.

Vol. XV. NEW YORK, NOVEMBER 2, 1898. No. 17.

ELECTRICITY

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4021 Cortlandt.

SUBSCRIPTION RATES:

United States, - - - - - - -	$2.50
In Clubs of Five or More, - - - - - -	2.00
Foreign Countries, - - - - - -	4.50
Single Copies, - - - - - -	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Another Reduction in the Cost of Electric Current.

The consumers of electric current in New York City are apparently about to reap the benefit of a competitive warfare. Some weeks ago we referred editorially to a new schedule of rates just issued by the Edison Electric Illuminating Company, and now their rival, the United Electric Light & Power Company, have gone them one better and reduced their rates to the ¾ cent basis. This reduction means that hereafter current will be supplied for incandescent lighting for 15 cents a kilowatt hour as against 20 cents a kilowatt hour now charged by the Edison Company under their new schedule.

These cuts in rates are undoubtedly the result of keen rivalry, although both companies claim that the reductions are due to the fact that at the present day, owing to improved apparatus, current can be supplied much cheaper than formerly. In any case the competition between these two electrical companies will unquestionably be felt by the gas companies, thus forcing them to take a hand in the warfare and likewise reduce rates.

On the one cent per hour basis an incandescent light is about equal in cost to gas at $2 a thousand. Electric light at ¾ cent per hour will be equivalent to gas charged for at the rate of $1 per thousand. The schedule recently issued by the United Electric Light & Power Company, however, places the cost of a light if used in excess of three hours at one-quarter cent per hour, which means that gas would have to be furnished at about 50 cents a thousand in order to compete with it.

The wholesale rate under the new schedule is ten cents a kilowatt for the first three hours of daily use and five cents a kilowatt for all use in excess of that time. Thus at ten cents a kilowatt a consumer would be paying the same as though gas were being used at the rate of $1 a thousand, whereas the price after the first three hours would about correspond to gas at 50 cents a thousand. The reduction in arc lighting is about on the same basis as incandescent, or 15 per cent lower than the former rate.

The plant of the United Electric Light & Power Company is comparatively small, having at the present time but an aggregate output of 15,000 horse power, the territory which it supplies extending from the Battery to 137th street from river to river. We understand, however, that arrangements are being made to increase its capacity from 15,000 to 27,000 horse power in the near future. As stated in our former editorial, it is the evident intention of the electric light companies, by the reduction in rates, to try and induce housekeepers to substitute electricity for gas, not only for illuminating purposes, but for cooking as well.

Where this rate war will end is hard to see, as it is now rumored that the Edison Company is contemplating a further reduction in its price for current to meet the recent cut of the United Electric Light Company. In any case, however, the consumers of either electricity or gas will probably be benefited.

* * *

Electrolysis.

Elsewhere in this issue will be found an article by Mr. A. A. Knudson entitled "An Electrical Survey in the Borough of Manhattan, New York City." This is the first time to our knowledge that a thorough survey of this nature has been made in New York, although other large cities, such as Boston and Chicago, have carefully examined into this important subject of electrolytic action set up by stray currents. Mr. Knudson's paper is well worthy of careful perusal by all those interested in the subj ct of electrolysis, and his tests made on the Brooklyn Bridge are especially interesting and timely in view of the discussion which arose last January as to whether or not sufficient current was finding its way to the metal portion of the structure to seriously affect the stability of the anchorages. From numerous and careful tests made, and from a careful examination of the plans of the anchorages, Mr. Knudson gives it as his opinion that the stability of the structure is not seriously threatened, apparently taking the same view of the matter as Electricity in an editorial of our issue of January 5.

The question as to whether cast-iron is subject to electrolysis is taken up by Mr. Knudson and ably discussed. He says:

"One of the bridge officials informed me that a certain authority had reported that electrolysis would not attack cast-iron, consequently their cast-iron anchor-plates were exempt from such danger. In the light of recent experience in other cities, that theory is now untenable."

He then goes on to quote from various reports showing conclusively that cast-iron pipe has been affected by electro'ysis in other cities. As may be recalled, this question as to whether cast-iron was subject to electrolytic action or not was brought up last February by the following statement of Mr. C. B. Martin, the electrical engineer of the Brooklyn Bridge:

"This insulation of the bridge is accomplished by the fact that the cables or connections of the bridge are fixed in the masonry at the anchorages, which are made of cast-iron. Cast-iron, as was shown by the exhaustive report of the subway commission,

which dug up pipes all over the city, is impervious to electricity."

We took exception to this statement, and in our issue of February 9 said:

"Mr. Martin's last statement regarding cast-iron would seem a rather curious one. It is unquestionably true that corrosion does not take place anything like so quickly with iron as, for instance, with lead, for while an ampere of current will dissolve in a year approximately 75 pounds of the latter metal, this same current will dissolve in the same space of time but 20 pounds of iron. Experience has shown, however, that cast-iron is by no means exempt from electrolytic action, and several photographs were exhibited at one of the meetings of the American Institute of Electrical Engineers a few years ago of cast-iron pipes taken from the ground at Milwaukee which were terribly pitted, and it was further stated that sections of this main had to be renewed, owing to electrolytic corrosion, three times in the course of two years."

We are glad to see that Mr. Knudson bears us out in our statement, as the Brooklyn Bridge officials appear to be still laboring under this delusion regarding the insulating qualities of cast-iron.

All sorts of remedies have been tried to prevent electrolysis, and only lately it was announced that a well-known engineer had invented a special generator which will prevent the escape of current, but in our opinion the solution of the problem lies in a greater expenditure of money to ensure an uninterrupted return, or metallic circuit.

* * *

Two New Systems of Telegraphy. Since Professor Morse transmitted between Baltimore and Washington the appropriate sentence "What hath God wrought" there have been innumerable improvements made in telegraphic apparatus. Some years ago it was found possible to transmit two, and later even four messages over a wire at the same time, known as the duplex and quadruplex systems. Devices of this nature are now in use in many telegraph offices and have justly been considered a giant stride in the development of telegraphy, enabling as they do a saving of both time and money. Two new systems are now however being experimented with which, providing they prove commercially successful, will mark another epoch in the history of telegraphy. One of these systems, known as the multiplex and invented by Professor Henry A. Rowland, will we understand shortly be given a trial between New York and Philadelphia over a line belonging to the Pennsylvania Railroad. By means of this device eight telegraphic messages may be sent over the same wire at the same time, four in each direction. This is accomplished by means of a keyboard at the transmitting end somewhat resembling that of a typewriter. The messages at the receiving end may either be recorded on a sheet of paper or upon a tape similar to that used in the ordinary ticker service. The advantages claimed for this system of telegraphy are, first, that no skilled operator is required at either end of the line, and secondly, that an enormous amount of time and money may be saved by transmitting eight messages simultaneously over the same wire. In a recent interview Professor Rowland is credited with the following statement: "There is no longer any question of the value and thorough utility of the machine, and many experienced telegraphers who have seen it work pronounce it absolutely perfect. An ordinary typewriter operator can send messages at the rate of forty words a minute, while all the time seven other messages are going over the wire, each separate and distinct from the others."

The other system previously referred to and known as the duodecaplex system was invented by a Frenchman, M. Mercadier, and is now being experimented with on an extensive scale over a line connecting Paris and Bordeaux. As many as twelve messages, it is claimed, may be simultaneously sent over the same wire by means of ordinary Morse transmitters. At the end of the line each operator is provided with what the inventor calls a monotelephone but which in reality differs little from an ordinary telephone receiver. The system is so arranged that each transmitter sends its message to its corresponding receiver, this being brought about by the use of interrupted currents. Each transmitter receives its current through a tuning fork having a special note, the vibration being maintained ele trically. These vibrations generate a current of the proper period, causing resonance at each application in the proper receiving circuit, which is adjusted for this especial period and no other. The signals are of course read by ear, little difficulty being experienced in so doing. The signals, it is alleged, divide up at the receiving end very perfectly, an operator at one receiver only being aware that other signals are being transmitted by an indistinct murmuring, not sufficiently loud to be bothersome.

Of the two systems, that invented by Professor Rowland would seem the best adapted for practical use, and certainly the most economical to operate, requiring as it does no expert telegrapher, and furthermore requiring at the most but one person at the receiving end, whereas the duodecaplex system would require at least twelve skilled operators. The development and practical application of these two systems will undoubtedly be watched with interest by the scientific world.

Under the Searchlight.

Notes and Comments on Various Topics.

THE St. Paul *Pioneer Press* publishes a certificate of amendment of the articles of incorporation of the Butte General Electric Company to the effect that the government of that corporation and the management of its affairs shall be vested in a board of not less than three, nor more than five directors, each of whom shall be a stockholder, and in the following officers, namely, a president, vice-president, treasurer and secretary, etc. To all of which our old friend H. M. Byllesby, being duly sworn according to law, on his oath saith that he, the said H. M. Byllesby, is president of the Butte General Electric Company, that he has read the foregoing certificate by him subscribed, and that the facts therein stated are true.

* * *

MR. NIKOLA TESLA has again alarmed his friends by announcing that he has discovered a means by which any amount of power can be transmitted electrically from its source to any part of the world without the use of wires, that is, by a system similar to wireless telegraphy. He asserts in a published communication that he has invented apparatus capable of generating electrical pressures vastly in excess of any heretofore used and that the current can be conducted to a terminal maintained at an elevation where the rarefied atmosphere is capable of conducting it freely; then at a distant point where the energy is to be used commercially to maintain a second terminal at about the same elevation to attract and receive the current and to convey it to earth through special means for transforming and utilizing it.

The difficulty with the recent extraordinary "inventions" of Mr. Tesla is that they do not seem to amount to anything more than astounding pen sketches and startling illustrations in the yellow journals. Several months ago we were told in double-leaded display type that Mr. Tesla had harnessed the sun and intended to erect a plant somewhere on Long Island to focus the solar rays and utilize them on a scale sufficient to turn all the machinery in the State of New York; then came the statement that he had gained control of the magnetic forces of the earth and could actually wobble the globe; following this was his discovery of a process by means of which man could make himself practically immortal, and to relieve him of the necessity of his customary ablutions he subsequently hit upon a plan to electrically cleanse the body without the use of water. These are but a few of Mr. Tesla's later exploits in the field of research that have found publicity in the columns of the press and have then passed into mist, and few will doubt that the last of his discoveries will prove anything more than the vagary of an overworked imagination.

* * *

AT the opening of the Brunswick Traction Company's new trolley line between Bound Brook and Plainfield, N. J., on the morning of October 29, the feature of the occasion was the running of the first car through Lincoln by Mrs. Emma Engel, president of the Borough Council. With her was Mrs. Flora P. Wrench and Mrs. Olivia Hazzard, also members of the council. On reaching the station at Lincoln, Mrs. Engel formally completed the line by driving a nickel spike into a tie. All this goes to show that the fair sex in that locality are apparently as expert in electrical and mechanical matters as in politics.

The General Electric Company's Dividend.

As we stated in our "Notes for Investors" last week, the General Electric Company has declared a dividend on its preferred shares, and the dividend is now officially announced as 11.66⅔ per cent. This is the first distribution on account of the accumulated dividends, which up to August, 1898, amounted to $1,527,885.33. The intention of the company is to pay the remainder of these accumulated dividends in installments and at the same time to pay the current dividends at the rate of 7 per cent. per annum on the preferred stock as reduced by a vote of the stockholders on August 17 of the present year. It is officially stated that the earnings of the company since the meeting at Schenectady in August last aggregate $500,000, and from this have been deducted debt and interest charges aggregating $150,000, leaving $350,000 available for dividends. The dividend of 11.66⅔ per cent., payable November 15, will require $297,640 for its payment, leaving due on the reduced preferred stock 48.22⅓ per cent., which must be paid before dividends are resumed on the common stock. The circular issued to the stockholders in which the dividend payment is announced says:

"Your board of directors has resolved to begin the payment of the unpaid accumulated dividends and the current dividends upon the preferred stock of the company. These dividends now amount to:

"1. Unpaid accumulated dividends amounting in the aggregate to $1,527,885.33 for the period commencing July 1, 1893, and ending August 17, 1898 (the date of the reduction of the capital stock), being dividends at the rate of 7 per centum per annum for the period named upon the par amount of the preferred stock prior to the reduction, namely, $4,252,000. As each share of the reduced preferred stock represents one and two-thirds shares of the preferred stock as the same stood prior to the reduction, the amount payable upon each share of the reduced preferred stock in respect of such unpaid accumulated dividends will be $59 89.

"2. Current dividends at the rate of 7 per centum per annum upon the par amount of the reduced preferred stock after August 17, 1898.

"Your board of directors has accordingly declared a dividend of $11.66⅔ per share on the reduced preferred stock, payable on and after November 15, 1898, to the holders of the preferred stock of record at the close of the transfer books on the fifth day of November, 1898. The amount of this dividend equals the unpaid accumulated dividends upon the preferred stock for the year beginning July 1, 1893, and ending June 30, 1894."

Meeting of the New York Electrical Society.

The 190th meeting of the New York Electrical Society was held at the Pearl street sub-station of

the Edison Electric Illuminating Company in Brooklyn on the evening of October 27. Two hundred and forty persons were present, each of whom on reaching the Pearl street station was presented with a programme informing him to which party and section he belonged. After an address by Mr. W. S. Barstow, in which the history and general evolution of the Edison system in Brooklyn was touched upon, the assemblage was divided according to their programmes into two parties, and each party into a number of sections, the latter being under the guidance of one of the Edison Company's employes. The first party then took trolley cars to the Union central station at Bay Ridge, returning by way of Station A, formerly known as the Citizens' station, while the second party first inspected Station A and then visited the Bay Ridge station. A collation was served to both parties.

Special cars were run to the New York end of the Brooklyn Bridge to accommodate the New York members, who reached the city shortly after midnight.

Through the efforts of Mr. George H. Guy and the courtesy of the Edison Electric Illuminating Company, and especially Mr. Edgar Allen Doty, the gathering was undoubtedly one of the most successful and enjoyable the Society has ever undertaken.

At the business meeting, which took place in the early evening at the Pearl street station, 30 new members were elected.

Proposals Invited.

The Bureau of Supplies and Accounts of the U. S. Navy Department is inviting sealed proposals until November 15, inst., for furnishing the Navy Yard at Portsmouth, N. H., with a quantity of electrical apparatus, including two 1,000 ampere single pole double throw machine switches; one 1,000 ampere Weston illuminated dial ammeter; one 150-volt Weston illuminated dial voltmeter; one ground detector switch; one 3-point voltmeter switch; two 500-ampere double pole double throw feeder switches; two 300-ampere double pole double throw feeder switches; four 200-ampere double pole double throw feeder switches; one double pole lightning arrester; one steam engine, to be of sufficient size to drive one direct connected 100 KW. generator at a speed of 250 revolutions per minute; to supply and install on the extended plate of the engine one 100 KW. dynamo of sufficient capacity to supply 100 KW. at 115 volts for ten hours without an increase in temperature in the armature, the dynamo to be of the multipolar type and compound wound; one 40 HP. motor; two 25 HP. motors; one 15 HP. motor, and one 5 HP. motor.

Prospective bidders desiring to bid on this important work can obtain detailed specifications, blank forms of proposals and other information upon application to the Paymaster General of the Navy, Washington, D. C., or to the Navy Yard at Portsmouth.

Meeting of the American Institute of Electrical Engineers.

The 125th Meeting of the Institute was held at 12 West 31st street on Wednesday, October 26, President Kennelly in the chair. A paper was read by Mr. A. A. Knudson on "An Electrical Survey in the Borough of Manhattan, New York City." The discussion was opened with a communication from William Maver, Jr., and continued by Townsend Wolcott, Jesse M. Smith and others.

The president announced that a Committee on Cooperative Research had been appointed in accordance with instructions from the council. The committee consists of Dr. A. E. Kennelly, chairman, Prof. W. A. Anthony, Dr. F. B. Crocker, Dr. C. T. Hutchinson, Dr. Samuel Sheldon, Chas. P. Steinmetz and Prof. E. Thomson. The purpose is to formulate a system of experimental research, by submitting to various colleges and universities various problems which are of practical importance. The investigations are to be made, as a part of undergraduate, graduate or post-graduate work, under competent supervision. The committee starts off with a list of sixteen subjects and will expect members to send in others which may occur to them in the course of their practice. The results when received, if deemed important, will be published in the Transactions. The plan is receiving hearty support.

At the meeting of the Executive Committee in the afternoon the following associate members were elected:

John McL. Murphy, Electrical Engineer Safety Third Rail Electric Co., New York.

F. K. Vreeland, Second Asst. Engineer Crocker-Wheeler Electric Co., Montclair, N. J.

J. E. Woodbridge, Editor *Electrical World*, New York.

The following associate members were transferred to membership:

C. H. Wordingham, City Electrical Engineer, Manchester, England.

William Stanley, Electrical Engineer and Inventor, Pittsfield, Mass.

AN ELECTRICAL SURVEY IN THE BOROUGH OF MANHATTAN, NEW YORK CITY.*

Showing Results of Stray Current Measurements Between Electric Railways, Underground Pipes, Etc., Also Results of Tests on the Brooklyn Bridge.

BY A. A. KNUDSON.

The corrosive effect of straying currents upon underground metallic structures is now so well known and understood that obviously there is no need to dwell upon this fact as a reality, but rather it is the purpose of the author to show from actual tests some of the locations and characteristics of the stray currents in New York City.

About eighteen months ago the question was raised by some of the municipal officers of this city as to the possibility of electric currents leaking or straying to underground pipes from the conductors of the "open conduit" electric railway on Lenox avenue, and adjoining streets at that time, as applications had been made to extend this system.

This matter was investigated at that time by the author, and some of the results becoming known to one of the officers of this Institute, he suggested that with some additional tests and the whole presented in a paper it would prove of interest to the members and perhaps throw further light on this interesting subject.

I have since made a number of additional tests throughout the city, from Harlem river to the Battery, between various metallic structures such as "L" (elevated railway) pillars, surface railways, water pipes, etc., and give the results here, trusting that they may prove acceptable, and possibly of some value.

Previous to making any tests on the Lenox avenue line, we had a well settled theory that in a double conductor system, as this is, very little if any of the current could be found diverted from the conductors to water or other pipes underground in its vicinity.

The tests were begun on Lenox avenue near the Metropolitan Company's 146th street power station, and continued south. From the first, unmistakable signs were encountered of railway current leakage from the rails of this road to both water and gas pipes, the sudden fluctuation of the voltmeter needle proving this beyond a doubt. It was noticed, however, that when a Lenox avenue car passed there was no advance of the needle as should be expected, and when two cars passed, going in opposite directions, there was no advance of the needle at the moment; continuing down the street and testing at each fire hydrant and gas post the voltage tended to increase upon nearing 135th street. The readings during these tests were as follows, the rails being positive to the water and gas pipes:

Location.	Water.	Gas.	Remarks.
145th street....	1/3 volt.	1/3 volt.	
188th "	2/3 "	1/6 "	
18[illegible]th "	2/3 "	2/3 "	
135th "	1/5 "	1/5 "	During this test no trolley car in sight on 185th st.
135th "	2/3 "		Test repeated when 135th st. overhead trolley car crossed Lenox ave. tracks.
125th "	1/2 "		
116th "	1/3 "		
109th " and Columbus ave.	1/3 "		

It was apparent from these tests that the most, if not all, of this leakage came from the Union Railway Company's line, operating the overhead trolley system, a branch of this road running through 135th street, and thereby crossing the rails of the Metropolitan Company's tracks at Lenox avenue. This seemed the more certain from the fact that the maximum reading (2/3 volts) was obtained when a Union Railway car was crossing the rails at Lenox avenue, or was quite near. Further proof, however, was necessary to determine if that company was responsible for all or only a portion of this current escape; advantage was therefore taken of the period when the Union Railway cars stopped running for the night, at 1:30 A.M., to make some further tests.

At this time there were no fluctuations of the needle whatever, and consequently no sign of a trolley current escape from the rails to underground pipes. Tests were made over the same route as during the day, as well as at other places, but although the Lenox avenue line was running (they have an all night service) no evidence could be obtained of current straying from those conductors to either water or gas pipes. What we did find, however, worthy of mention, was another current, emanating from an entirely different source, passing from the water pipes to the rails, the pipes this time being *positive*, which, as will be perceived, was the reverse of the polarity found during the day. This current was as perfectly steady as if from a galvanic battery. The difference of potential, however, was low; in some places one-thirtieth of a volt only was found, while in others the reading was two-thirtieths. In my efforts to identify this current I consulted the manager of the power station which supplied current to the Lenox avenue road, and he obligingly offered to shut down the plant for half an hour dur-

135th "	"L" + to Hydrant 1/3 volt.	1/30 " "L" + to Hydrant. Night readings steady throughout.

* A paper read at the 128th Meeting of the American Institute of Electrical Engineers, New York, October 26th, 1898.

ing that portion of the night when traffic is the lightest and give me a chance to re-test. This was done between the hours of 2:30 and 3 A. M., when both of these electric roads were then shut down so that no possible current could come from either one. The same steady current was found, however, as before, passing from the water pipes into the rails. The

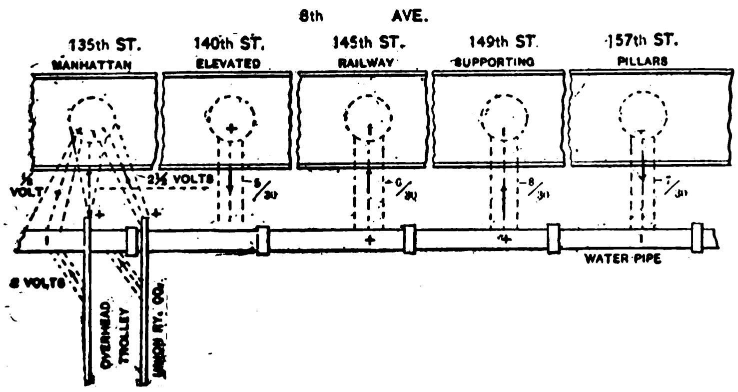

Fig. 1.

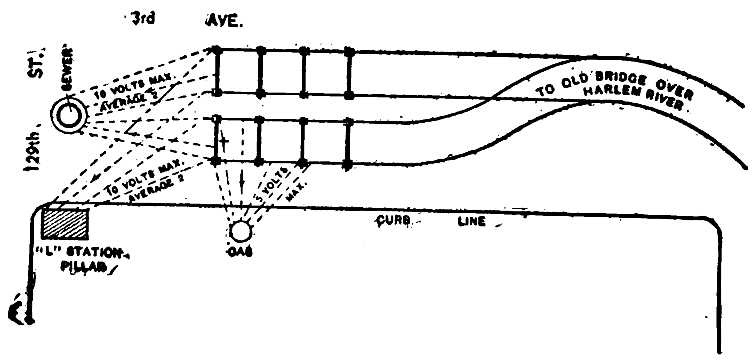

Fig. 2.

voltmeter proving insufficient as a means of completely identifying this current telephone receivers were used, and with one at each ear there was no difficulty in recognizing the familiar sing of the incandescent dynamo. This test with the telephone was repeated several times by my assistant and myself so that there could be no possi bility of error.

It appears from the tests made that an open conduit system, or one in which an insulated metallic return is used, effectually confines the current to the conductors provided for it. For this reason it is preferable to the ordinary ground return, especially in large cities, where the space below the streets is so largely occupied with various lines of iron pipes, more or less subject to electrolytic action.

The distances the overhead trolley current would sometimes reach were shown by a rise in voltage when a Union railway car crossed the tracks of the Lenox avenue road at 135th street. This was found as far down as 116th street, where the latter branches east and west; in fact there was no portion of this road where these trolley current fluctuations could not be obtained when cars were passing through 135th street.

Desiring to learn the difference of potential between the elevated railway pillars, and water pipes, with the Union railway, if any, in this part of the city, tests were begun at 157th street (Harlem river) on the Eighth avenue line and continued down as far as 109th street, which is the western terminus of the Metropolitan Company's open conduit system. Rather than make this paper monotonous with long tables of tests, some plans have been prepared of different locations in the city, showing where these tests were made, and giving the difference of potential at the points indicated. It may be well to state here that the voltmeter used was a Weston two scale; the lower scale reading to 5 volts with 30th divisions; this scale was used in most of the tests, and accounts for the record being given in a number of cases in thirtieths of a volt. The upper scale read to 150 volts in 1 volt divisions.

The following is a general description of the method of procedure, touching in detail at such points as may be of interest.

The starting point as already stated was at 157th street; from this point down to 135th street the tests are given in a table, as well as in plan, Fig. 1, the table giving both day and night tests for comparison while the plan gives the day tests only.

The Union railway (overhead trolley), heretofore spoken of as passing through 135th street, terminates at Eighth avenue; in fact the ends of the two trolley wires of that road are supported by being attached to the "L" structure, which as is well known passes through that avenue.

Referring to the table, it will be noticed that the reading at 157th street shows that the night test was the same as during the day. It was afterwards discovered that the last car of the Union railway had not then left the track, which accounts for this reading being higher than the other, as well as a trolley variation being shown. All of the other night tests, however, showed the same indications of an incandescent current as were found on Lenox avenue as well as at several other places. One feature worthy of notice in the day test, shown in the plan as well as the table, is the change of polarity found at different points on this section of the road.

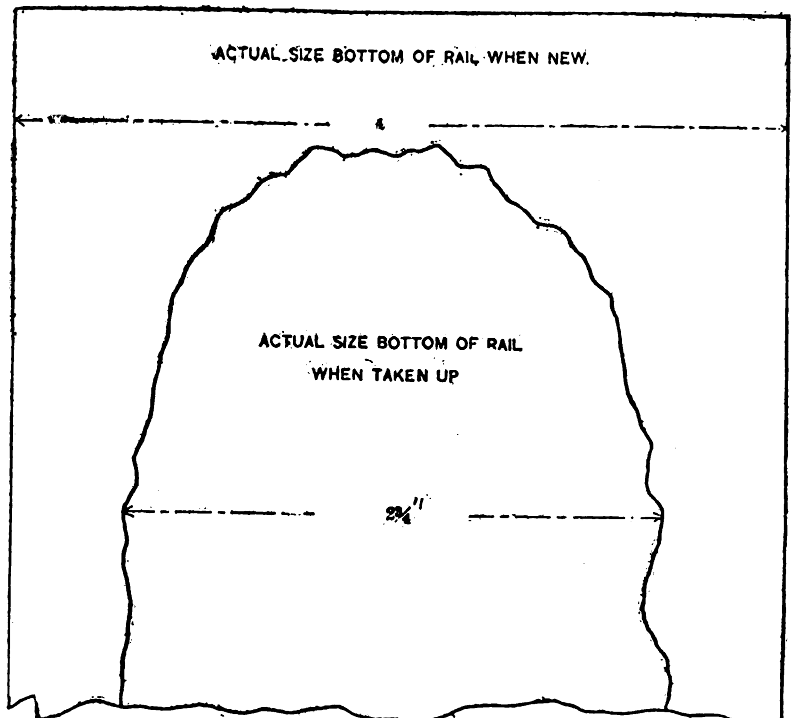

Fig. 3, Plan.

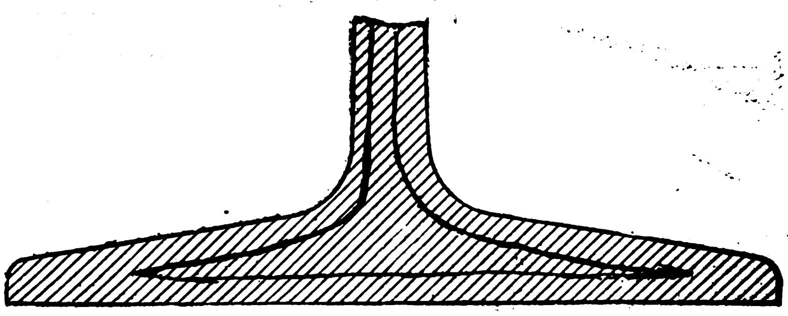

Fig. 3. Section

The current passes into the water pipes and "L" structure from the rails of the trolley road at 135th street (they being positive) from 2 to 2½ volts maximum, then along the pipes for five blocks to 140th street, then reverses and passes along the "L" structure for another five blocks to 145th street, where it again reverses and takes the water pipes to another reversal at 157th street.

The cause of this erratic jumping of the railway current up some pillars and down others may be explained in two or three ways, two of which I will mention:

1. Proximity of water pipes to the "L" structure, at some points being closer than at others, offering a more favorable path for this portion of the current.

2. The current passing into the water pipes at 135th street as well as the "L" structure at the same polarity, and possibly at a higher voltage at times to water, may cause this change in polarity at different points along the line.

A few days ago tests were made over this same section of road with almost identically the same readings in each case as prevailed over a year ago. It was noticed, however, that the terminal rails of the Union Railway Company at 135th street and Eighth avenue had recently been replaced by new ones, which appears to be a good illustration of "cause and effect."

Similar conditions also prevail on the section of road below 135th street down to 109th street. At this point the "open conduit" road has its western

terminus. Day tests have shown a maximum reading of one-third of a volt, the rails being positive to the "L" pillar and to water, the night test when Union railway was not running two-thirtieths steady, showing plainly that the current was from that road.

Attention is now directed to the east side of this part of the city where another branch of the Union railway is located. Tests made here show even more pronounced results than at the branch running through 135th street to the west side. It may be stated that the power station of this road is located on the Bronx river in Westchester County.

Something more than a year ago when these tests were made, this branch had a terminus at Third avenue and 129th street, immediately in front of the "L" station, the cars then passing over the Harlem river at the old wooden bridge, which is now being removed. The cars now pass over the public bridge recently opened, to the new terminal at Lexington avenue. Fig. 2 shows the location of the terminal when these tests were made, as well as the difference of potential.

It will be noticed that the maximum reading here was 10 volts, rails positive to "L" pillar, sewer and gas. A test was also made on the Harlem bridge

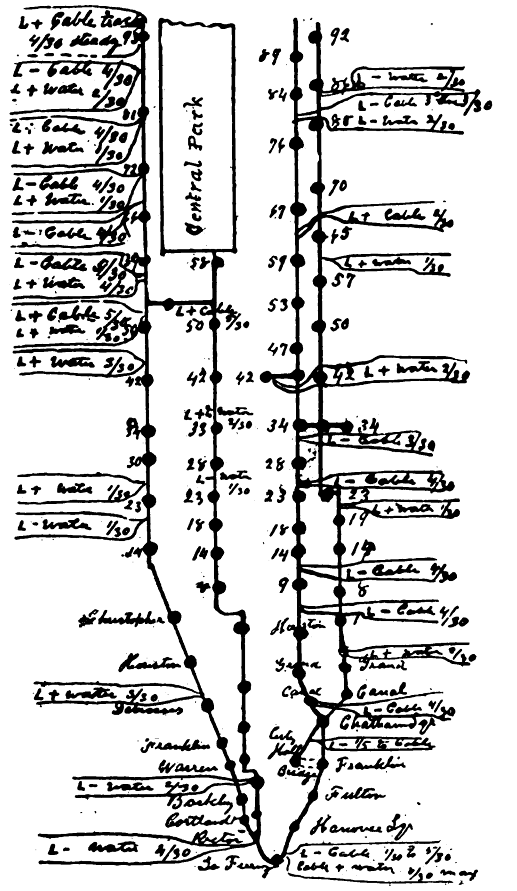

FIG. 4.

which showed the same reading, except it was made to gas only, no other pipes being at hand. A few days ago this locality was visited with a view of obtaining any further items which might be of interest for this paper, and workmen were found engaged in removing the rails of this very terminal.

Information was therefore obtained as to the results of electrolytic action on these rails (they having been positive). An impression was taken on paper of the exact size and shape of the end of one of the four rails which composed that terminal switch, the ends of the other rails all being in just about the same condition. Fig. 3 shows a comparison of the size and shape of the rail when new and its present condition; the position of the outlines as to each other being about as shown. From the condition of these rails now, it is quite plain that a large amount of metal has been removed from them by electrolysis. The original size of the rails was furnished by the company supplying the rails, they being about 70 lbs. to the yard; furthermore, the bottom sides of all these rails were cut by the current down to knife edges for several feet back from the ends. These edges were irregular in shape and somewhat jagged in appearance.

Another feature of interest is the condition of the cross-bars or tie-rods which keep the rails in position.

These bars, which were originally $1\frac{1}{2}''$ wide by $\frac{3}{8}''$ thick, were nearly all so eaten away that the middle portion was missing, the ends protruding from the rails at from 6" to 12".

Further tests were made in this part of the city, but being not specially important are omitted until 93d street is reached, from which point to the Battery a plan is given, showing the locations where tests have been made, their voltage and polarity. These tests refer mostly, as you will notice, to the incandescent current, passing at low voltage, ranging from 1-30 to 1-5 of a volt. One feature worthy of attention is the lowest reading being generally found at the "L" stations, between pillars under the stations and water pipes. This is accounted for by the fact that as there are water pipes supplied to most if not all the "L" stations they would make a fairly good electrical connection with the structure itself, and therefore not much difference of potential could be expected. This point also suggests a method for remedying this condition of affairs. Coming down the west side of the city, I was surprised to encounter a full fledged trolley current in the extreme lower part of the city. The first intimation was found at Rector and Greenwich streets; it became more pronounced in the vicinity of South Ferry where in testing between the rails of the Metropolitan cable road and an "L" pillar a variation of from 1-30 to 8 30 volts was found, the rails positive, and the same reading between the rails and water pipes.

Just why there should be indications of a trolley current in this part of Manhattan Island was difficult to understand, but after making further tests coming up on the east side this current was found to come from the Brooklyn bridge. Having pointed out how an overhead trolley using the water pipes and incidentally the rails as a return, such as is operated on 135th street, can spread its influence, so to speak, for a distance of over twenty blocks in either direction north and south, through various pipes, railway structures, etc., the existence of this current from the bridge permeating underground metals through a large portion of the lower part of the city is accounted for.

The tests were continued at the New York entrance of the bridge, at the pillars which stand in the street just west of the Third avenue cable railway I found the readings as follows: At one pillar a maximum of 3 volts, average $1\frac{1}{4}$ volts, pillar positive to Third avenue cable rails. At another, practically the same reading. Further up Park Row, at the corner of Chambers street, pillar positive to cable rails, 1 volt maximum; water positive to cable rails, $\frac{1}{2}$ volt; pillar positive to water, $\frac{1}{5}$ of a volt.

All of these tests were made nearly a year and a half ago. A few days ago tests were made over this same ground, and at places where a difference of potential of 3 volts maximum existed at that time it is now found to be 3 1 5 volts, pillars positive as before to rails of Third avenue cable and also to water pipes, showing in all probability that this current has been during all this time actively and unceasingly passing down the pillars which support the "L" station at this place, as well as the bridge crossing the street, and out from their foundations to other metals, as stated, with now a fifth of a volt more for good measure.

In the light of present knowledge on this subject the very serious question presents itself to any practical mind here present, in what condition would we expect to find the anchor bolts and iron foundations of these pillars if excavations were made at their base?

In Mr. Farnham's excellent paper read before this Institute four years ago, he showed that but a small fraction of a volt was necessary to establish electrolytic action between metals.

What then can be expected from an incessant action of from $1\frac{1}{2}$ to 3 1-5 volts jumping out of these foundations during the past year and a half or perhaps two years?

Further tests at the New York entrance of the bridge at pillars nearest the four loop tracks show that they are negative to rails of these tracks with maximum voltage of $3\frac{1}{4}$, an estimated average of $2\frac{1}{4}$. These tests were made on three different days at different times of the day, the highest maximum reading as above being taken at 4:45 P. M. The other tests were made during the so-called rush hour between 5:30 and 6 P. M., where a maximum reading of 2 1-5 volts noted at track 1 did not vary much from the tests made another day at from 2 to 2:30 P. M. at track 4, where the voltage was found to be $2\frac{1}{2}$ maximum. Previous to any use of electricity for operating cars on the bridge it had been

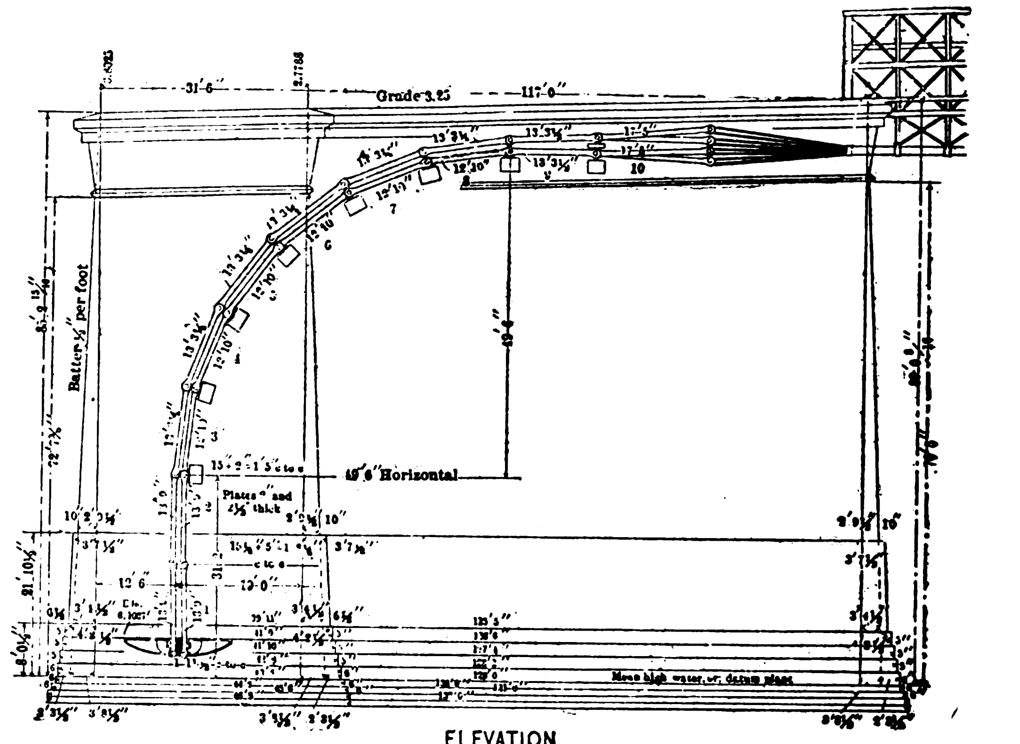

FIG. 5.

known that currents were escaping to that structure from trolley lines in Brooklyn, and passing over would find their way through the city by underground pipes, etc., and thence crossing the river arrive back to the power station in Kent avenue.

The polarity of both of these railway systems now operated on the bridge indicates that these currents escape from their lines, but it is also quite likely that currents are even now coming over the bridge as they were a year ago. Only an extended investigation would determine these points, even if it were desirable that they should be known.

Let us now take up the investigation made on the bridge to determine if possible the movements of straying trolley currents and their possible effect on the cable terminals. In view of the importance of this matter I regret not being able to make it more thorough than here stated, as it would involve not only a fortnight's work at least, but the shutting down of the bridge plant for a time, which could hardly be expected under the circumstances. Such facts are represented however as it was practicable to obtain. Recognizing the necessity of having every detail as to the construction, location, etc., of these

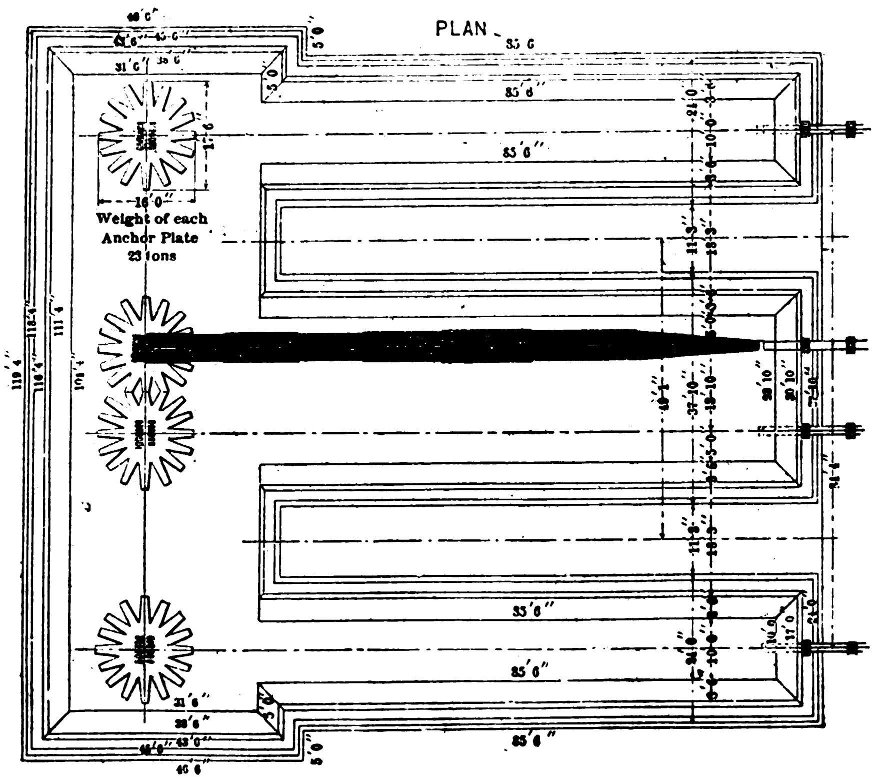

FIG. 6.

terminals before being able to intelligently consider the matter, plans prepared by the bridge engineers were obtained which are given in Figs. 5 and 6. These show the exact construction of the cable terminals and anchor plates, besides other information regarding construction, all of which is from an official source.

In regard to the construction of the cable terminals: as most of us know, the main cables are made up of eighteen strands, or smaller cables, which are practically continuous, the wire running back and forth from New York to Brooklyn, passing through the holes at the ends of heavy steel bars or links at each place, and the ends of the single wire being finally fastened by a rigid screw coupling. These two rows of steel bars of nine each, which are attached to the cable strands, one row placed over the other, as shown in Fig. 5, pass down with a graceful curve into solid stone masonry to the anchor plates, and are secured to them by heavy steel bolts passing through the eyes at the ends, as shown in the figure. The anchor plates are in shape somewhat longer one way than the other (see plan), each being a single piece of cast-iron weighing twenty-three tons.

(*To be continued.*)

ON THE TRANSMISSION OF POWER BY TWO AND THREE PHASE CURRENTS.*

BY ANDREW STEWART.

The subject of power transmission by means of polyphase currents has of late been receiving a great deal of attention and has led to the discussion of the relative merits of two and three phase currents for that purpose.

The subject may be divided into two divisions—(1) The transmission and distribution of light and power in cities; and (2) in factories. The first case may again be divided into two sub-divisions—(*a*), the transmission of energy from a central station to a number of sub-stations containing rotatory converters, converting the alternate current to a direct one, feeding a low tension network for lighting or traction; (*b*), the transmission of energy from a central station to a number of transformer sub-stations, feeding a low tension alternate current network.

The case of many large cities would be met by—(*a*) where they are already equipped with low tension direct current plant, which is in many cases outgrowing the limited amount of ground available in most cities; while (*b*) more nearly represents the present single-phase system of distribution, with which many provincial towns are equipped. The only difference is that the system, being multiphase, a large motor load could be carried.

The question is, under what circumstances is it desirable to choose a two or three phase system?

That both are successfully supplying light and power does not mean that they are equally suited to the purpose, and it is the object of this short paper to consider both systems as nearly as possible on their merits.

In Europe the three-phase system seems to get the preference. Although two-phase plants are in operation, they are not so numerous as three-phase; while in America both two and three phase systems are very numerous.

The advocates of three-phase currents state that by that system, as applied to motors, a more uniform turning effort is secured, and the power factor is higher. While the former may be conceded, it may be pointed out that the turning effort of two-phase motors is uniform enough for all practical purposes. As for the latter statement, it is open to considerable doubt. It is true that one prominent European manufacturer of polyphase machinery shows a slightly higher power factor (about 2 per cent.) for three-phase machinery. But a well-known American firm shows the same power factor for two as for three phase plant, and there seems no theoretical reason for any difference in their power factor.

The chief disadvantage of the three-phase system is its liability to become unbalanced, due to unequal loading of any of its two sides. This may be met by taking the same care in arranging the lamps as would be taken on an Edison-Hopkinson three-wire system, or by using a special balancing transformer. However easy these remedies may seem, it is admitted that in large cities serious unbalancing may occur. The experience of many three-wire systems in large cities is not by any means reassuring to anyone who proposes to use three-phase distribution. Owing also to the three circuits being electrically interlinked, it is impossible to control one phase independent of the other. Thus the application of the three-phase system seems to be confined to simple power distribution in large units, or to any purpose where the current may be kept approximately the same in all three lines, thus meeting the requirements of case (*a*) to a very large extent.

The necessity, however, for maintaining a fairly well balanced line renders it unsuitable for the general distribution of light and power.

Two-phase seems to present many advantages, especially where single-phase is already installed, as it is easy to feed a single-phase network, as such, from a two-phase generator; there is also an entire absence of balancing troubles, as a two-phase generator may be run with one phase fully loaded and the other half-loaded, with scarcely any variation of the pressure, while even this may be eliminated by regulation. The ease with which one phase may be controlled independent of the other renders it extremely useful in supplying a mixed system of light and power, as in such cases it would be practically impossible to get the load equal on both phases. Nearly all the regulating devices used on single phase may be used on two-phase, thus rendering easy its introduction into places where single-phase is already installed. Indeed, two-phase seems to give all the advantages of multiphase distribution, with the flexibility and ease of control so characteristic of single-phase, thus meeting the requirements of case (*b*).

In factories where the distribution of light and power by polyphase currents has been coming to the front of late, there seems in many cases little to choose between two and three phase currents. In most cases a large motor load has to be supplied, and, as the lighting load goes on and off with fair regularity, and is generally under the control of the engineer in charge, unbalancing troubles are not so much to be feared. Thus three-phase seems to meet all requirements. In numerous cases, however, electric welding has to be considered, and as it is desirable, wherever possible, to use only one type of plant inside a works, the suitability of the generator to supply current for welding transformers is important. Here two phase scores decisively. It is a matter of no difficulty to supply a welding transformer from one phase of a two phase generator, while to do the same from a three-phase generator would be to upset the balance of the entire system, causing lamps on one side of the network to burn dim, arc lamps to flicker, and a general derangement of the entire system.

One important point should not be overlooked—that is, cost of copper. This is greatly in favor of three-phase, while, on the basis of maximum stress on insulation, the direct current, three-wire system is most advantageous.

Although, as will be seen, three-phase has such a large advantage over its rivals, in the matter of cost of copper this does not have much influence in the case of power transmission in factories, where the cost of copper seldom exceeds 30 per cent. of the total cost, and, when compared with flexibility and ease of control of two-phase, it will be no great advantage to give three-phase the preference, except where very large amounts of power must be transmitted.

It will be seen from the foregoing remarks that both two and three phase systems have distinct merits of their own, and in course of time will each have their own position in the engineering world.

Meanwhile, I hope that these remarks will serve to clear up any misunderstanding relating to the important subject of power transmission by polyphase currents.

DIESEL'S RATIONAL HEAT MOTOR.*

BY E. D. MEIER.

(*Concluded from page 248.*)

I have just received a paper from a noted Austrian engineer, Mr. Emil Krause, written after a careful personal inspection of the Diesel motor at Augsburg. Mr. Krause is known beyond the limits of his own country as an expert on boiler construction and boiler management, and his position is such as to qualify and bias him rather as a champion of the steam engine than otherwise. Thus, when I quote his conclusions, I am giving you the convictions of a man whose interest is, if anything, inimical to Mr. Diesel, but whose professional integrity compels him to acknowledge excellence where he finds it:

"I saw such a motor at work in the Augsburg Machine Works last fall, and must state that it impressed me as a completely designed and finished machine.

"(1) The working process, such that heat is supplied only at high temperatures, fills the requirements of a rational heat motor better than any previous heat engine.

"(2) The temperature at which the addition of heat begins is entirely independent of the process of combustion, and is so high that the efficiency, even when a minimum of heat is supplied, cannot fall below that fixed by this initial temperature.

"(3) The influence of the temperature of combustion on the thermal efficiency is so small that within certain limits this efficiency actually increases with the excess of air in which combustion is effected.

"(4) The regulation of the motor can be consequently accomplished without affecting its economy.

"The first petroleum engine embodying these principles has placed the Diesel motor at the head of all petroleum motors up to date. The same success is probable for the Diesel gas engine; work on this is progressing, and everything indicates that a new success for Diesel will shortly be recorded."

It was Diesel's first intention to build a motor with three cylinders embodying compound compression and compound expansion, and one of this type has been built at Augsburg, and is to be thoroughly tested on producer gas. But the development of the single-cylinder type has been so satisfactory, and the demand has become so great, that at present the German shops are busy to their fullest extent building this simpler form. As this form has reached an absolute efficiency of 30 per cent., and is in every way a simple and practical machine, there is at present no reason for developing the compound motor. The cut here given (Fig. 1) represents the first of these 20 horse-power motors, built by the Nürnberg Machine Works. In appearance it resembles a vertical marine engine; a strong base-plate supports the the main journals of the crank-shaft, outboard bearings being provided for the shaft extensions which carry the fly-wheel and pulley. Bolted to the base-plate is a stout A frame containing the guides. In the rear leg of this frame, a small air-pump is supported. On top of the frame is placed a cylinder open at bottom. Its top is closed by a head cast in one piece, in which are contained one suction valve for air, one discharge valve for spent gases, and a needle valve for the fuel. The admission to the casing of this fuel valve is controlled by a stop valve which can be instantly closed to shut off the supply of fuel. Besides this, there is a starting valve used only in starting the engine. Cylinder and air-pump are water jacketed. This water jacket was not used in the earlier experimental engines, but is found advantageous in keeping the temperature of the working parts uniform. As the temperature of combustion is so much lower than that of the explosion type of engines, a much smaller amount of water suffices for this. In the earlier German engines, the main shaft and crank are bored for water cooling. This, however, grew out of the practice of Krupp's Steel Works of boring all small shafts produced. The practice has been discarded in England and in America as unnecessary. The air-pump is driven by a set of levers attached to the main cross-head. Conveniently placed to one side is an air vessel, known as the starting tank, connected by copper pipe to the air-pump, and to the fuel valve casing.

The operation is as follows: On one down-stroke the main cylinder is completely filled with pure air, the next up-stroke compresses this to about 35 atmospheres, creating a temperature more than sufficient to ignite the fuel. At the beginning of the next down-stroke, the fuel valve opens, and the petroleum, atomized by passing through a spool of fine wire netting, is injected during a predetermined part of the stroke into this red-hot air, resulting in actness. In this regulation resides a great advantage for the Diesel motor. The full charge of air being always supplied for complete combustion, it matters not whether the governor permits one or fifty drops of petroleum to enter the working cylinder at each motor stroke, the combustion is always complete. Thus variations in excess of air over that theoretically necessary from 26 to 116 per cent. have been measured, and the analysis of the spent gases shows no trace of unburnt carbon or hydrogen. It is hard to conceive a more perfect combustion than that which takes place when fuel is sprayed, finely powdered or atomized into red-hot air just beginning to expand. To stop the motor it is only necessary to close the valve which admits the petroleum into the fuel valve casing. The valve gear consists of a series of cams placed on a shaft journalled on brackets cast on the cylinder.

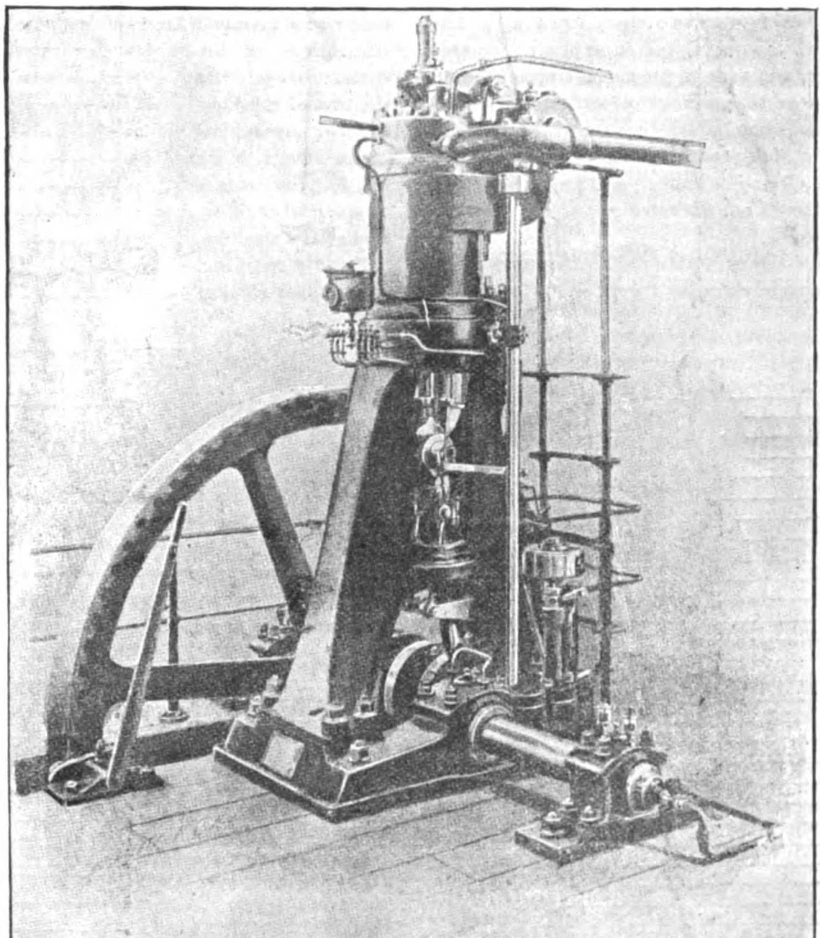

FIG. 1 —Diesel Motor—Perspective View.

combustion controlled as to pressure and temperature. This injection is made possible by the air in the starting tank, which is kept by the small air-pump at a pressure some 5 to 10 atmospheres greater than that in the main cylinder. A small quantity of this air enters with the fuel charge, which it atomizes as described. When the motor is running at full load, a very small quantity of injected air suffices, and the pressure in the air tank steadily rises. At half load, with less fuel injected, more air passes in. For this reason, the starting tank is made large enough to equalize these differences, and a small safety valve is provided on the air-pump.

The petroleum is pumped into the fuel valve casing by a small oil pump bolted to the base-plate. This pump is arranged to pump a fixed maximum quantity of petroleum. A by-pass is provided so that this whole quantity or any portion of it can be returned to the supply tank. The governor controls the action of this by-pass valve, closing it just long enough to compel the exact quantity of the fuel required to pass into the fuel valve casing. As this requires only the movement of a small light wedge the regulation is accomplished with great ex-

In starting the motor a hand lever is pulled to one side throwing all these cams, except the exhaust valve cam, out of gear, and throwing a special cam into gear with the starting valve. A few strokes of the petroleum pump by a hand lever inject a small quantity of petroleum into the fuel valve casing. The fly-wheel is thrown over by a lever a trifle beyond the upper dead point. The fuel throttle valve is opened, and by a turn of the hand-wheel communication is established between the air tank and the starting valve. A single charge of highly compressed cold air enters the cylinder, sufficient to give two revolutions of the fly-wheel at moderate speed. At the close of the first revolution the starting valve cam is automatically thrown out and the other cams into gear, thus on the second revolution a full charge of air is drawn in and compressed, and in less than thirty seconds the motor is running at full speed.

It will be noted from Lord Kelvin's clear analysis of the working process of the Diesel engine that Mr. Diesel makes a sharp distinction between the temperature of ignition and the temperature of combustion; the first is a constant value at each pressure

* From the Journal of the Franklin Institute for October.

and dependent only on the physical qualities of the fuel—the higher the pressure the lower the temperature of ignition. The temperature of combustion on the other hand is variable, depends on many conditions, and especially on the quality of the air by which the combustion is maintained, but it is always higher than the temperature of ignition.

Diesel's radical departure from all previous practice is in generating a combustion temperature by mechanical compression of pure air, utilizing this temperature to ignite the fuel, and by so introducing the fuel that the heat lost by expansion is practically balanced by the heat added by combustion.

Before the completion of this perfect engine certain critics of Diesel's theories contended that the dimensions of the cylinder and all other working parts would become so great as to make it impracticable to build such engines. But in Diesel's engines the increase and the decrease in pressures are so gradual that there is no shock. The change from one to the other is always accomplished at a dead point. In all motors relying on explosion for their moving force, and even in the steam engine, there is a direct blow at the moment of ignition or admission. I present here a drawing on which indicator diagrams of a high-pressure steam engine, of an explosion-type oil motor and of a Diesel motor have been drawn based on the same piston displacement (Fig. 2).

Diesel's and the explosion-motor diagrams can be directly compared since both work on the four-stroke cycle. The steam-engine diagram should be quadrupled. This disposes of the objections just referred to.

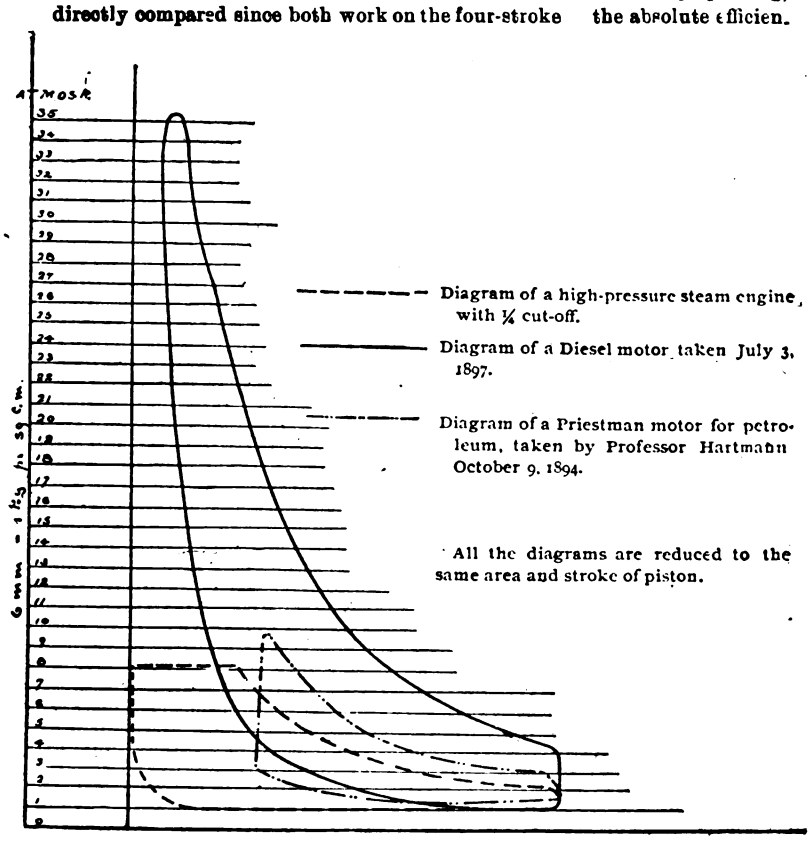

FIG. 2.—Comparison of diagram of a Diesel motor with diagram of a steam engine and of an explosion-motor.

These second and third diagrams (Figs. 3 and 4) are graphic comparisons of the Diesel motor with a number of the best petroleum motors as to economy in fuel and volume swept by the piston per second. They are given on the authority of Prof. Hartmann, well known as a careful and conscientious observer in this field.

The abscissæ represent piston displacement in liters per second, the ordinates petroleum consumption in grams per hour, both figured on the effective or BHP. The full lines (Fig. 3) embrace the results for full load, the dotted lines (Fig. 4) those for half load. The comparison is between engines which burn ordinary safe lamp petroleum or kerosene; results obtained on benzine or naphtha are not considered, since motors depending on such dangerous fuels can never be generally adopted for industrial purposes. The calorific value of these highly inflammable and explosive liquids is no greater than that of safe kerosene or of fuel oil.

You will notice that we find the Diesel results in both cases near the apex of the angle. Or, plainly put, both at rated capacity and at half load the Diesel motor shows the smallest cylinder dimensions and the least expenditure of fuel.

Remember that the others represent the best results from engines carefully developed and improved in all mechanical details, while the Diesel motor is but the third one ever built, and that in its construction the practical realization of the theoretical cycle was the primal consideration, mechanical improvement being left for the future commercial exploitation of the machine.

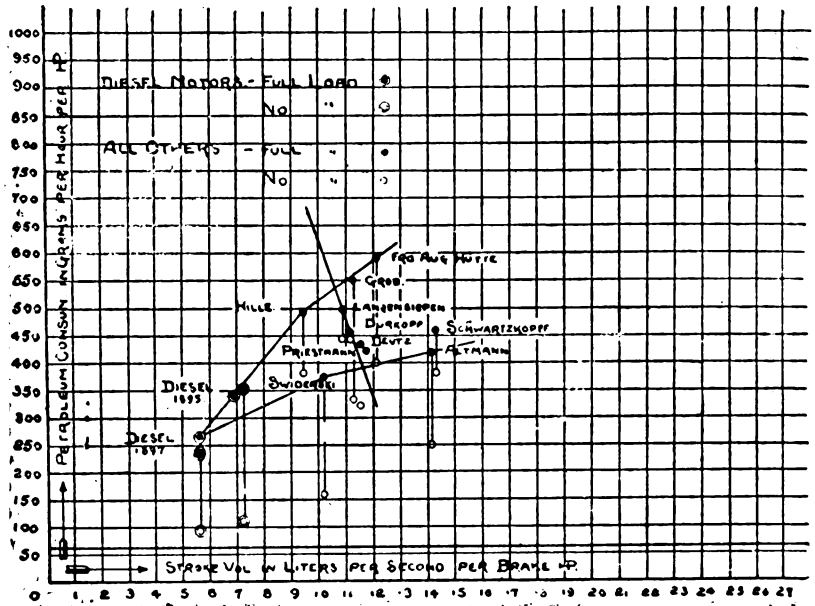

FIG. 3.—Graphic comparison of the performance of Diesel motors and best previous types of (explosion) oil motors.

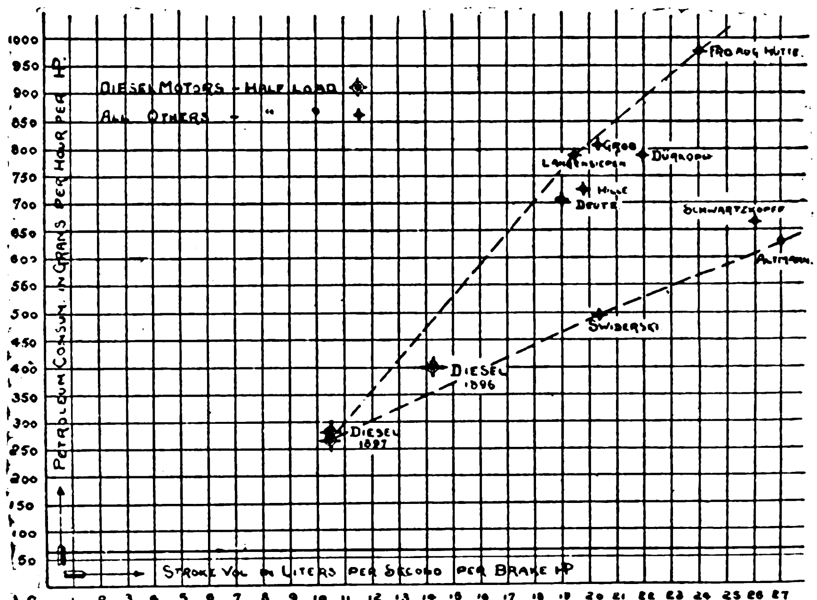

FIG. 4.—Graphic comparison of the performance of Diesel motors and best previous types of (explosion) oil motors.

Broadly speaking, the absolute efficiencies of the best-known heat engines of to-day range about as follows, taking into account actual calorific values of the fuel and effective or brake horse-power:

	Per cent.
Small auxiliary steam engines, pumps, etc.	.6 to 1
Plain slide valve engines in good condition	3 to 5
Single-cylinder Corliss engines	6
Compound-condensing engines	8
Reheating-compound or triple-expansion steam engines	12
Best oil engines (explosion type)	16
Best gas engines (explosion type)	19
Diesel motor	28 to 30

All these are compared when running steadily at full load or rating at point of best economy.

But in a large majority of the applications of all these prime movers the exigencies of the service require them to be run frequently at three-quarters and at half load for a large part of their daily service.

It is conceded that in most engines the internal frictions or mechanical losses are a fixed amount, so that a loss of 15 per cent. at full load becomes 30 per cent. at half load. And thermal losses increase even more rapidly; for instance, in steam engines by cylinder condensation. In gas and oil engines the absolute efficiencies have in some cases shown measured loss of nearly 60 per cent. In the Diesel motor the thermal efficiency is shown to increase with decreasing loads, thus counteracting in a marked degree the loss in mechanical efficiency which it shares with the other machines. From a number of carefully-checked tests, I found the average drop in absolute efficiency from full to half load to be only 12 to 13 per cent. in the Diesel motor.

So promptly and easily does it respond to a change of load, that a sudden addition of 30 per cent. to the electrical load on the Diesel motor at the Electrical Exposition at New York, by the throw of a switch, was not noticed by observers of the engine or the lights, though promptly registered by the ammeter.

For variable loads, then, the Diesel motor will show in practice a much greater superiority over all rivals than that apparent from the tabular figures just given.

The Diesel motor has been fully developed as an oil engine. At first it was tested only on ordinary lamp petroleum, such as is used in every household.

But in November last I sent a barrel of American gas oil and four barrels of American fuel oil to Augsburg and Nürnberg, to make conclusive tests in regard to its reliability and economy on those cheap fuels. A series of tests was made, which gave the gratifying results that the economy was the same as on refined petroleum, and the combustion so complete that no fouling of cylinder, valves or exhaust-pipe occurred.

Encouraged by this, the German factories made tests with a cheap fuel oil, distilled from bituminous shale, and called "Solar Oil" in Germany. The result was so satisfactory that motors have since been sold guaranteed to run on these cheap oils, and they are doing this with perfect satisfaction.

American fuel oil is sold, delivered on track in tank cars and tank wagons, at prices ranging from 1.6 cents to 2 cents per gallon in the West, and from $2\frac{1}{2}$ cents to 3 cents in the East; based on these prices, and allowing the high average of 240 grams per BHP. hour, a 100 horse-power Diesel motor will consume about 15 cents' worth of fuel per hour. With coal at $2.80 per ton, the fuel cost per hour for 100 BHP. in a good steam engine will be about $54\frac{1}{2}$ cents for a slide valve, $43\frac{1}{2}$ cents for a Corliss, and 22.4 cents for a triple-expansion engine, and to this should be added a fair proportion of the fireman's wages, and for coal-passing and ash-hoisting, none of which charges would be incurred where the Diesel motor is used. Weighing all these facts, it becomes easy to understand the wonderful and unprecedented progress made by Diesel's invention in Europe.

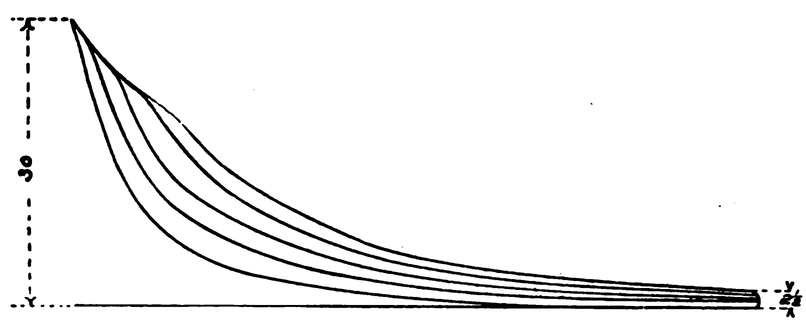

FIG. 5.—Diesel motor used with gas-indicator diagrams when regulating ½ millimeter = 1 kilogram = 14·7 pounds.

Up to date he has licensed sixteen large machine shops to build his motor, and a conservative estimate of the amount of capital now specially devoted to this work in Europe places it at between four and five million dollars. The invention comes to our shores, not, as so many do, in its experimental stage, but in a complete form, so far as stationary motors are concerned. Designs for railway, street car and marine motors have been made in Germany and England, and they will probably have passed through their experimental stage by the beginning of next year. The adaptation of the stationary motor to gas is practically completed, and a progressive series of tests on various kinds of gas will be run in Augsburg during the summer.

I take pleasure in presenting an enlarged view of an indicator diagram (Fig. 5) taken from the motor while running on Augsburg city gas, merely to show you that the same beautiful and economical cycle is possible with gas as with petroleum.

The work of experimenting, developing and testing has been performed with proverbial German thoroughness. American methods of manufacture, with special tools, gauges and templates arranged to turn out a large number of duplicates of each size, will soon bring the motor into general use in the United States. To do this the same broad policy of dividing the work among a limited number of first-class and well equipped manufacturers, which works so well in Europe, will be adopted here.

The freedom from smoke, ashes, soot, etc., the absolute immunity against explosion, the great saving in space, in labor and in fuel, will soon bring this rational heat motor into general use in our large cities, at first for small and medium powers, but gradually for far larger ones; and it is my opinion and firm belief that, before the end of the century, the name of Rudolf Diesel will be written on the same scroll with that of James Watt.

LEGAL NOTES.

At the Trial Term in Rochester, N. Y., Justice Nash granted a non-suit in the case of Isaac Hooper against the Rochester Gas & Electric Company. Hooper sued for $2,000 damages for alleged negligence of the company, because while driving along the street an arc light fell on him, injuring his head.

At Watertown, N. Y., on the 20th ult., a verdict for plaintiff was rendered in the suit of Charles Cohen against the Thomson-Houston Company. The action was brought to recover $150,000 for services rendered in South Africa and for damages by reason of an alleged wrongful dismissal as agent of the company. The Watertown *Times* in its comments on the case furnishes the following particulars:

"The real defendant in the action is the General Electric Company, for that corporation is to all intents and purposes the successor of the Thomson-Houston Company. The evidence from which the jury rendered its verdict was almost entirely letters that passed between the parties. Mr. Cohen was in South Africa, working in the interest of the defendant, for nearly four years. There he was confronted with a conservatism which demanded a great deal of missionary work. The letters gave the jury a very clear idea of the magnitude of this work and the almost insurmountable obstacles which had to be overcome. His claim is that when this conservatism was in a measure removed, when it seemed very probable that Mr. Cohen would soon realize something from his incessant labor, he was told that there was no contract between him and the company, and that the implied contract was at an end. It was claimed on behalf of Mr. Cohen that the reason of this was that the Thomson Houston Company had been merged into the General Electric Company, which found that it could get the business with less expense by some other method than through Mr. Cohen. He had exploited the goods at the expense of a great deal of money and over three years of hard labor.

"The company claimed that it had the lawful right to sever its connection with Mr. Cohen, inasmuch as, after three years, he had not succeeded in getting any business for them.

"An appeal will probably be taken in the case, but it is the opinion of many lawyers, who have watched the case, that it will not succeed. Justice Hiscock was very careful in the trial of the case to hold the attorneys back from presenting incompetent evidence, and his charge was a model of its kind. He examined carefully the law that was presented to him by the attorneys, and every point was closely analyzed without prejudice to either side. The only ruling on which it seems an appeal can be taken is his refusal to hold as a point of law that the discharge from employment of the plaintiff by the defendant was a lawful one. He held that it was a question to go to the jury under instructions by the court.

"The next step to be taken is the appointment of a referee to assess damages, and the attorney who is selected will have steady employment for some time."

CANADIAN NOTES.

The Cataract Power Company of Hamilton, Ont., have connected their transformers with the city wires of the Hamilton Electric Light & Power Company, and the incandescent lights will be supplied with electricity developed at Decew's Falls, which are about 34 miles distant from the city.

An important question is to come up at the next meeting of the Hull Electric Company of the city of Hull, opposite Ottawa, in Quebec province. A project is on foot to alter the cars now in use so that they can be run at 40 miles an hour. By doing this less cars will, it is calculated, be required, and therefore fewer men will be employed.

Mr. W. C. McDonald, the millionaire tobacco manufacturer of Montreal and the generous benefactor of McGill University of that city, has again demonstrated the interest he takes in that institution of learning by presenting to the department of electrical engineering the sum of $30,000 with which to purchase the best and most modern electrical apparatus. This gift will enable the department to acquire much-needed apparatus, and it is said that when all is in place the department will take first rank among the many departments of electrical engineering on this continent.

It is confidently predicted that the valley of the St. Maurice river, which is now a densely-wooded wilderness, will in ten years be a hive of industry. Three immense enterprises are already at work—the Shawinigan Power Company, Lawrentide Pulp Company and the Canada Iron Furnace Company. The first-named company is preparing to develop electric power in enormous quantities, available for industries which will follow and for transmission to Montreal, Quebec and other manufacturing centers. The natural lay of the land and water is such that power can be developed at a minimum of cost. The company is proceeding to install a plant which will be able to develop 30,000 horse power, to be eventually increased to over 100,000 horse power. The engineers estimate that 200,000 HP. can be developed.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Birmingham, Ala.—The North Birmingham Electric Railroad, running from Birmingham to North Birmingham Park, a distance of four miles, has been in operation for several days, the street dummy that formerly plied between these two points having been abandoned. The Birmingham Traction Company, which acquired the seven-mile Gate City dummy line and converted that into a modern electric road, is also the owner of the North Birmingham line.

Bluffton, Ind.—A new electric railway project is in the air here which involves a direct line from Fort Wayne to Indianapolis. The new road will start from Alexandria, run to Gaston, in Delaware county, and thence to Hartford City. From Hartford City the line will run parallel with the Lake Erie & Western road to Fort Wayne, the northern terminus, taking in Montpelier and Bluffton.

Brooklyn, N. Y.—The Flushing and South Shore Line of the Long Island Railroad, which is to run from Flushing to Jamaica and to Far Rockaway, Rockaway Beach and other beaches, is to be equipped with electricity, and the road it is expected will be running next summer. Work on the line is already under way. It is proposed also to extend the Huntington electric railroad to Huntington Bay and Cold Spring Harbor.

Elwood, Ind.—Charles L. Henry of Anderson; Thomas Day of Indianapolis, and T. C. Burkley of Hartford City, met here a few days ago with others interested in the electric line from Elwood to Indianapolis via Perkinsville and Noblesville, and it was decided to build the road. The farmers along the route are anxious for it and have offered substantial assistance.

Gloucester, Mass.—The Gloucester "Breeze" of October 24 says: "A. R. Hallowell, ex-superintendent of the Gloucester Street Railway, and Samuel L. Gibson of this city sailed from New York Saturday for Ponce, Porto Rico. It is said that Mr. Hallowell goes there as the representative of a New York electrical syndicate with the hope of securing franchises for an electrical street railway. The syndicate he represents has ample capital and will construct a road equal to the best in this country. It is reported that President Fer-

guson of the local street railway company is much interested in the enterprise."

Chicago.—The Illinois Traction Company, a new corporation, proposes to operate an electric street car line between Grand Crossing and South Chicago. It is said to be backed by a number of capitalists who are abundantly able to equip and operate the line. John M. McCabe is acting as agent of the company.

Eau Claire, Wis.—One of the most complete systems of street railway that can be found in the West is that owned and operated by the Chippewa Valley Electric Railway Company, which controls about twenty miles of track, operating its handsomely appointed cars in the cities of Eau Claire and Chippewa Falls and connecting the two cities, 12 miles apart, by an interurban line. The power is furnished from Eau Claire and is sufficient to propel cars thirty miles an hour. C. E. Kelsey of Eau Claire is president of the company.

Honolulu, Hawaii.—A traction company has been organized in this city to be known as the Honolulu Rapid Transit & Land Company. Its officers are: President, L. A. Thurston; vice-president, J. B. Castle; secretary, J. A. Gilman; general manager, C. G. Bellentyne. The general manager is expected to arrive in New York about December 15 to make purchases for the road, which is to be operated by electricity, but by what system is not yet definitely known.

Joplin, Mo.—The Southwest Missouri Electric Railway, perhaps the longest continuous electric line in the world, has been reorganized and the controlling interest has passed into the hands of Joplin and Harrisburg, Pa., capitalists. A. H. Rogers, of Joplin, the promoter of the road, was elected president and treasurer; E. Z. Wallower, of Harrisburg, vice president; A. G. Knisely of Harrisburg, secretary; George J. Paul, of Aurora, Ill., superintendent. The Southwest Missouri line extends from Galena, Kan., through Central City, Joplin, Webb City, Carterville and Prosperity, Mo., to Carthage, Mo., a distance of twenty-seven miles, passing through the heart of the great lead and zinc mining belt.

Montgomery, Ala.—The "Advertiser" states that an electric railroad is to be built from this city to Wetumka. The road will pass Pickett Springs, and part of the plan is to make an attractive artificial lake there and summer resort. In fact the expectation is to develop the line as a resort route. Among the local people mentioned as being interested in the scheme are McD. Cain and W. C. Bibb.

New Hartford, N. Y.—The application of the Sauquoit Valley Electric Street Railroad Company for permission to build and operate a street car line through this village has been granted.

Newport News, Va.—It is announced that a Baltimore syndicate has purchased the bonds of the Newport News and Old Point Railway & Electric Company to the extent of $800,000, and also $400,000 of the cumulative stock of the company, and the understanding here is that important extensions are contemplated, but in what direction is left to conjecture.

Rome, N. Y.—Philadelphia capitalists are said to be negotiating for the purchase of the street railroad here, with the intention of changing its motive power to electricity and extending the system to Sylvan Beach by way of the Rome custodial asylum, Verona, Oneida and Durhamville, the extension to be equipped for freight as well as passengers.

Tonawanda, N. Y.—The Buffalo & Lockport Electric Railway and the Buffalo, Kenmore & Tonawanda Railway will be connected by means of a switch track to be laid along Delaware street, the trustees having granted a franchise permitting the Buffalo & Lockport company to build the switch.

Toronto, Can.—It is stated that H. A. Everett of Cleveland, O., is interested in a scheme by which Buffalo and Toronto would be connected by trolley roads. Mr. Everett is a large owner of shares in existing roads that would be included in the system, and it only requires the building of about 15 miles of new road to complete the chain.

Vicksburg, Miss.—The Vicksburg Electric Car Company are reported to have signed a contract at Chicago with builders for the construction of six miles of street railway in this city. Percival Steele of Chicago owns the franchise. The whole cost of the line will be about $150,000.

LIGHTING.

Boston, Mass.—On the 22d ult., Colonel S. M. Mansfield, chief of the U. S. Engineer Corps for this district, opened bids for the furnishing and erecting of electric lighting plants in the power houses of the new gun batteries at Grovers Cliff, Winthrop and Nantasket Head. The bids were as follows: Grovers Cliff—Electric Storage Battery Company, $1,468; General Electric Company, $3 295; G. M. Angier & Co., $2,385; Bibber, White & Co., $3,659; Almon, Sargent & Conant, $3,925; New Jersey Foundry & Machine Company, $3,549; Lord Electric Company, $2,972. Nantasket Head—G. M. Angier & Co., $2,610; Almon, Sargent & Conant, $4,175; Bibber, White & Co., $3,434; New Jersey Foundry & Machine Company, $3,772; Lord Electric Company, $3,092; General Electric Company, $3,650; Electric Storage Battery Company, $1,468.

Colville, Wash.—J. R. Cook and Paul Laplante will shortly apply to the town council for a franchise to put in waterworks and an electric light plant in Colville.

Edwardsville, Ill.—The electric light and ice plant of the Edwardsville Electric Light & Power Company was destroyed by fire on the 24th ult. The plant was valued at $40,000 and was insured for $16,000.

Greensboro, N. C.—B. S. Johnson and others, of Baltimore, Md., contemplate installing an incandescent electric lighting plant in Greensboro.

Hartford, Conn.—The Cromwell Water Works Company has bought the Allison Hammer Factory, which has been vacant for several years, for the purpose of establishing a plant for lighting the town of Cromwell by electricity.

Huntingburg, Ind.—This city proposes to have electric lights if a company will put in a plant and rent it to the city with the option of purchasing in ten years. The plant at the outset would be required to furnish about 500 incandescents for commercial purposes and 35 arcs for street lighting.

Independence, Mo.—W. T. Felton of Kansas City, representing a company of Kansas City capitalists, has filed in the city council an application for a 20-year franchise for a new electric light plant to be erected in this city.

Lodi, N. J.—The council has passed to third reading the ordinance granting a franchise to the Lodi Light, Heat & Power Company.

Merrill, Wis.—The plant of the Merrill Lighting & Railway Company was destroyed by fire on the 19th ult. The plant was valued at $10,000 and was insured for $3,000.

Richmond, Va.—The Richmond Paper Manufacturing Company has awarded a contract for installing an electric light plant at their mills in this city to the Electric Construction Company of Virginia. The plant is to be first-class in every particular, with direct coupled multipolar steel Diehl dynamos, and is to conform in every respect to the plant recently erected by the same company for the city of Richmond at the new pump-house.

Sumter, S. C.—The city will receive bids up to December 1 on a 10 or 15 year contract for 37 arc lights of 2,000 CP., and for about 160 incandescent lights. C. M. Hurst, city clerk, will furnish information.

Weedsport, N. Y.—It is reported that J. D. Edwards will have a partner from Syracuse in the business of furnishing Weedsport with incandescent electric lights for private use.

Westwood, N. J.—At a public meeting held here recently to discuss the question of lighting the streets, a vote was taken to ascertain the choice of the people as to the kind of light they preferred for the purpose, resulting as follows: for electricity, 50; gas, 18. Seven votes were cast for no light.

Whitesboro, N. Y.—At the special election on the 24th ult., to decide whether the village should be lighted by electric or Welsbach lights, the vote cast was in favor of electricity 119 to 32.

MANUFACTURING, ETC.

Cleveland, O.—Bids will be received until November 16 at the Cleveland State Hospital for two 50 KW. 110 volt direct connected dynamos to operate at 300 r. p. m.; one 10 HP. motor; one 7½ HP. motor; one 4 HP. motor; one 50 KW. dynamo, wiring, etc.; two automatic high speed engines, each to develop 75 HP. at ¼ cut off and 80 lbs. pressure, etc. General conditions and specifications will be furnished by the engineers, E. P. Roberts & Co., Osborn building, Cleveland.

Houston, Tex.—A company has been organized here to erect a handsome building for the purpose of exhibiting all kinds of manufactured products and novelties. It is estimated that at least 30,000 persons will visit the exhibition every month.

Newark, N. J.—Gould & Eberhardt are just shipping eight of their improved drills to the U. S. Government at Rock Island, Ill., and some for Brooklyn, N. Y. Also have a number of other Government orders for their patent extension base shapers for the various arsenals, as well as some automatic gear cutting machines. The works have been very busy for some time back working on orders for their improved tools.

North Adams, Mass.—A plan has been hit upon to keep the Hoosac tunnel clear of smoke. The plan is to build a hood over the central shaft of the tunnel and erect a mammoth centrifugal fan under the hood and draw up the smoke by suction through the operation of the fan. The fan will be so large that it will require a 25 horse power electric motor to run it and this is to be furnished by the Stanley Electric Company. The North Adams Electric Company will supply the current.

Richmond, Va.—The American Tobacco Company has installed a 120 KW. generator and sixteen electric motors in its factories in this city, to take the place of steam apparatus heretofore in use. The new machinery was furnished by the Westinghouse Company. Electric plants are being also installed at the factory and mills of the Virginia & North Carolina Wheel Company and at the works of the Richmond Guano Company.

Suffolk, Va.—David Reckard has established works here for the manufacture of dynamos and other electrical appliances.

Washington, D. C.—U. S. Consul J. C. Monahan at Chemnitz has furnished the State Department with an important report on "Opportunities for American Trade in Germany." He says: "Excellent opportunties are being offered here for the importation of American tools, electric appliances, and all kinds of articles used in the construction and equipment of railroads, etc. Everywhere from one end of the Empire to the other lines are being opened, extended or improved. It seems to me we might sell millions of marks worth of the wooden parts for cars as well as rails, wires, apparatus, etc. If we 'worked' this empire and the whole Continent as carefully as Germans 'work' the United States, from Portland Me., to Portland, Ore., our exports of tools and machinery here would swell within a few years to double their present proportions. Only a few of the 'bench men' know how much better are many of our tools and machines than those made in Germany."

TRANSMISSION PLANTS.

Denver, Col.—The Denver "Post" of the 18th ult. says: "The many schemes for harnessing the Platte and making it do Denver's drudgery work have come to a head and the Denver Power & Irrigation Company, a million dollar enterprise to furnish electric light and power to Denver, is fairly launched. The company plans to dam the South Platte river; to pipe the water thus dammed to Deansbury and then by the use of turbine wheels to generate power sufficient to furnish electricity to the street car lines of the city, to the Consolidated Electric Company, to all small manufacturers and to the proposed Denver & Cripple Creek Short Line Railroad. James E. and Walter Rhodes of Denver are among those behind the enterprise. They have carried out successfully power transmission enterprises of a similar character at Ogden, Utah, and Anaconda, Mont. The bonds of the company have recently been taken in the East as a result of the close of the war and renewed confidence in Western investments."

Kalamazoo, Mich.—The Kalamazoo Electric Company has a big scheme in view. It proposes to light nearly every town in Southwestern Michigan and furnish power enough for the operation of all the trolley cars in Kalamazoo and Allegan counties. The plan is to dam the Kalamazoo river near Allegan, and with the water power obtained generate electricity enough to light Plainwell, Otsego, Allegan, Battle Creek and other towns and the country between them and run trolley cars besides.

Leadville, Col.—Dr. M. J. Ricoff of London is in this city to arrange for the construction of an electric power plant at Malta, the power of which is to be utilized by mining men. Dr. Ricoff says the plant will be built if mining men guarantee their patronage. The doctor goes from here to Salt Lake to investigate mining property, and then goes to New York, there to report to his company.

Tacoma, Wash.—William T. Baker, president of the Snoqualmie Falls Power Company, has addressed a long letter to the mayor and council in which he presents his objections to several provisions of the franchise offered him by the council to supply electric service in this city. The council has refused to modify the franchise to meet Mr. Baker's views and are now considering the scheme of Mr. Talbot for a municipal plant, the power to operate which would be generated at the Puyallup falls.

COMPANY MATTERS.

Des Moines, Ia.—Amended articles of incorporation of the Des Moines Edison Light Company were filed with the county recorder in this city on the 19th ult. The principal change is in the amount of the capital stock which is increased from $136,000 to $450,000. The "Leader" says "the purpose is to further the consolidation of the electric lighting business in Des Moines. Besides the Capital City plant, operated by the gas company in conjunction with its business, there are two other plants in Des Moines which up to the present time have been conducted by two corporations, though in reality they have both been owned by the General Electric Company for the past eighteen months. They are the Fort Wayne and the Des Moines Edison. In the foreclosure proceedings against the Fort Wayne plant the General Electric Company, which owns all the stock of the Des Moines Edison, bought up the bonds and bid the property in for them. It is the purpose now to exchange these bonds for the stock of the Des Moines Edison Company and thus complete the consolidation of the two plants."

Madison, Wis.—The People's Electric Company, dealing in electrical supplies, has made an assignment. Liabilities, $8,500, and assets about the same.

New Brunswick, N. J.—The Brunswick Traction Company, which controls all the trolley lines in Middlesex county, N. J., and also lines in Somerset and Union counties, has been merged with the New York & Philadelphia Traction Company. Judge Gottfried Krueger of Newark, Andrew Radel of Bridgeport, and E. H. Radel of New Brunswick have purchased a controlling interest in the New York & Philadelphia Company. J. Blair MacAfee, vice-president of the New York & Philadelphia Company, will retain his office, and his company will be operated under the direction of the Brunswick Company.

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—The elevators in the Capitol will hereafter be operated altogether by electricity. The old mechanism was very primitive and many unfavorable comments were made on the subject by those who had most occasion to use the elevators. But now every

thing has been arranged in the most modern manner and there will be no occasion for complaint.

Chatham, N. Y.—The Chatham Electric Light, Heat & Power Company, which has recently constructed an electric light plant on the Kinderhook creek to operate the lights in Chatham, will also erect a mammoth grain elevator with a capacity of 100,000 bushels. All the machinery will be operated by electricity. The improvements are to be on an elaborate scale, making this the most extensive plant of its kind in Columbia County.

Troy, N. Y.—The Troy City Railway has effected a settlement with the heirs of a number of persons who were killed in the crossing accident at Cohoes on Labor day. The heirs of the three sisters who were killed received $3,000 in each case. A man whose wife and two daughters were killed in the collision received $10,000 as the representative of their estates. It is believed that the railway company will effect a settlement with those who were injured at the time of the accident, thus avoiding much litigation and possibly heavy adverse verdicts.

Oswego, N. Y.—The receiver of the Oswego Street Railway Company and the Lake Ontario and Riverside Railway Company advertises that all claims must be presented on or after the 14th day of November, 1898.

PERSONAL AND MISCELLANEA.

G. Mortimer Williams, general manager of the Birmingham (Ala.) Traction Company, has resigned, and been succeeded by George H. Clarke, superintendent of the company.

Clarence G. Davenport, formerly expert and agent of the General Electric Company at 44 Broad street, New York, who went to Porto Rico with the 1st Regiment Volunteer Engineers, died of typhoid fever at Ponce on October 26. He was an associate member of the American Institute of Electrical Engineers, having been elected November 21, 1894.

A press dispatch from Hudson, Mich., states that James Whitcomb of that town has invented an electric light which promises to displace the regular lights. It is fed by a current from a chemical, the light being similar to the regular incandescent light. Mr. Whitcomb has made arrangements with the Gilliland Electric Company of Adrian for the manufacture of the apparatus. It is stated in the same dispatch that experts in electricity pronounce the new light a success.

One hundred and fifty members of the electrical trades from New York, Boston, Philadelphia and Connecticut, accompanied by ladies, witnessed the performance of "The Fortune Teller" at Wallack's Theater, New York, on Tuesday night last week. The party, several of the men being bald-headed, occupied the first rows of the orchestra, and gave a hearty reception to Miss Nielsen and other members of the company. At the conclusion of the second act a bouquet of roses in which were placed six electric lights of three-candle power each, fed by dry batteries, was presented to Miss Nielsen. After the performance the entire party entered automobiles and were taken to the Waldorf-Astoria, where supper was served.

The Kansas City "Star" says it has discovered why the Metropolitan Street Railway Company stops running its cars after midnight. It says: "The explanation of the mystery is that the Metropolitan Company has felt that the midnight stoppage of cheap transportation has stimulated a disposition on the part of the Kansas City people to go home early in the evening. If owl cars were the rule young and thoughtless husbands and those who are old and cunning would find manifold and plausible excuses to remain down town until past the hour of midnight. When it comes to paying fifty cents and $1 for a carriage, even the most frivolous minded revelers have found reason to hustle around and catch the last car. Thus, all unknown to an ungrateful community, the Metropolitan Street Railway has established and maintained the sobriety and thrift of the male population of this town and saved many a a lone woman from sitting up, wearily waiting for her wandering boy or tardy husband. All honor to the thoughtfulness and philanthropy of the Metropolitan Street Railway, the good angel of Kansas City!"

A Denver electrician speaking of the numerous processes for the reduction of ores now being exploited in that city and basing their claims to recognition upon electricity, says that "electricity will only aid in the precipitation of gold that has already been discolved, and that no method had yet been discovered by which the values can be extracted directly from the ore by its use. Chemicals must first be used to extract the gold, electricity may then aid in collecting it."

Secretary Alger, when at Montauk, paid a high tribute to the members of the Second Regiment Volunteer Engineers. "This organization," said he "has always been found ready to perform any duty required of it. It has been given some very important work, and has never failed to do it in the best possible manner. There have been no complaints from its members, either about sickness or lack of food, and we have not been bombarded by showers of requests for discharges of the men. They have behaved like true soldiers, and I wish that we could always keep them in the service. They are genuine patriots, for most of the members of this regiment sacrificed good salaries to serve in the army. Some of the most eminent civil engineers, draughtsmen and electrical experts in the country are to be found in the regiment—men who were receiving salaries ranging anywhere from $5 to $30 a day before they entered the volunteer service."

RECENT COMPANY ELECTIONS.

Jamestown Street Railway Company, Jamestown, N. Y.—President, A. N. Broadhead; vice-president, L. B. Warner; secretary and treasurer, S. B. Broadhead; superintendent, G. E. Maltby; directors: A. N. Broadhead, S. B. Broadhead, William Broadhead, W. S. Cameron, L. B. Warner, F. E. Gifford, R. N. Marvin and O. E. Jones.

Lowell Lawrence & Haverhill Street Railway Company, Lowell, Mass.—President, G. H. Campbell; vice-president, Alfred A. Glasier; treasurer, G. E. Tripp; directors: Alexander B. Bruce, G. H. Campbell, William Endicott, 3d, Temple R. Fay, Alfred A. Glasier, Francis R. Hart, Arthur R. Robertson, Edwin S. Webster and Harry K. White.

Rockland & Abington Street Railway Company, North Abington, Mass.—President, A. L. Register; clerk, George W. Kelley; treasurer, Charles N. Cobb; directors: David Pepper and Albert L. Register of Philadelphia, Pa., George W. Kelley and John Spence of Rockland, Charles N. Cobb of Abington, A. H. Brooks of Boston, and G. F. Wells.

Tri-City Railway Company, Davenport, Ia.—President, E. E. Cook, Davenport; vice-president, F. C. Denkman, Rock Island, Ill.; secretary and treasurer, J. F. Lardner, Davenport; directors: the officers and W. H. Edwards of Rock Island and H. A. Ainsworth of Moline.

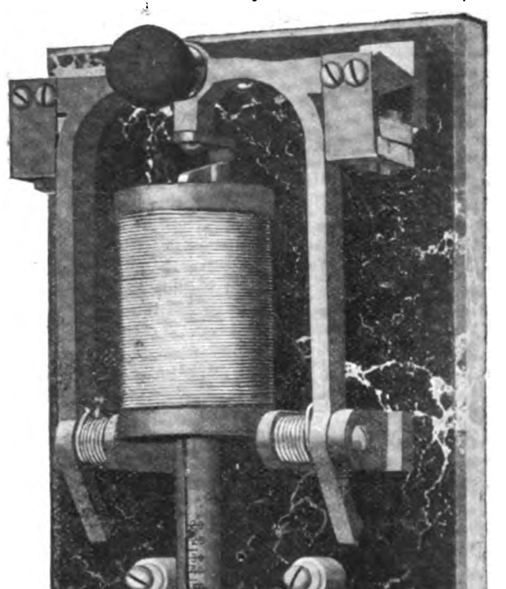
West Roxbury & Roslindale Street Railway Company, West Roxbury, Mass.—President, T. T. Robinson; treasurer, F. N. Terrell; directors: Robert Bleakie, J. S. Bleakie, Clifford Devens, R. B. Fairbairn and N. P. Whittemore.

COMMERCIAL PARAGRAPHS.

A New Circuit Breaker.

The cut presented herewith illustrates a new type of single pole circuit breaker manufactured by the well known firm of F. A. La Roche & Co., 13th and Hudson streets, New York City.

This circuit breaker is also made with over and under load attachments for motor work. It is especially adapted for high voltages ranging in the neighborhood of 2,000 volts, and is guaranteed to break 2,000 volts successfully without arcing at the clips. This feature is accomplished by the method in which the carbons are attached to the breaker. It will be noticed that the carbons are parallel to the clips, and as the breaker opens, the carbons attached to the blades open with a cam motion which keeps a rubbing contact on the stationary carbon until the blades themselves are well out of the clips and at a safe distance, then



the circuit is finally broken through the carbons and below the clips, so that no burning of the clips or blades can possibly take place. The blades are of the wedge type and close into "V" shape clips. These are laminated and flexible to an extent, so that they adapt themselves to the shape of the blades, and an absolutely tight contact is thereby formed.

The latch and trigger are made of case hardened steel and are of the compound lever type, so constructed as to permit of a very weak solenoid being used, as the force of the blow required to operate the breaker is very small. This method of construction is new in this style of instrument.

The hinge posts and blade arms do not carry any current, and it will be noticed by referring to the cut that there are two phosphor bronze springs in each hinge. These springs are quite weak and only strong enough to give the switch a sharp and quick break. Owing to the peculiarly shaped blades and clips, it is an absolute impossibility for the circuit breaker to stick, and the construction of the clips tends to throw the blades out of their own account. This breaker would really operate without these springs in the hinge, the springs being there only to assist in quickening the motion. On the bottom of the lever arms are two projections which are parts of the blade frame and come in contact with a buffer, so that when the breaker is opened and performing its function the blow on the hinge post is reduced to a minimum. Underneath the solenoid is a copper tube upon which is marked the calibration in amperes and fractions thereof. Upon the end of this tube is a milled head screw and nut, which admits of adjusting the circuit breaker to open at any desired point within its guaranteed high and low ampere ratings.

These circuit breakers are handsomely finished in copper throughout, no brass or iron being used. They are undoubtedly the neatest and most substantial circuit breakers on the market for motor work; they cannot fail in their operation and will perform their duty satisfactorily under the most trying circumstances. They are mounted on either white marble or marbleized slate bases as may be desired, and require no remounting, as each breaker is provided with binding posts, and will operate in a box or panel board requiring only 5 inches depth; it is simply necessary to run a wire to said binding post without any other connections or mounting.

Special care is taken to calibrate these instruments, and they are as reliable as any standard amperemeter; they are made in sizes from 15 amperes up to 500 amperes, above that the manufacturer recommends the "Victor" No. 1 circuit breaker or the "Ideal" circuit breaker, both of which are manufactured by the firm of F. A. LaRoche & Co., 13th and Hudson streets, New York City.

The Electric Appliance Company, Chicago, are meeting with great success in the sale of their combination fuse block and lightning arrester for telephone work. It seems to fill a large demand for an efficient device for protecting telephone apparatus, and the Electric Appliance Company have yet to hear of a single case where it has failed to operate in an entirely satisfactory manner.

INCORPORATIONS.

The Council Bluffs Gas & Electric Company, Council Bluffs, Ia. Capital stock, $250,000.

The Wisconsin Storage, Electric & Water Company, Plymouth, Wis. Capital stock, $25,000.

The Electric Therapeutic Manufacturing Company, Indianapolis, Ind. Capital stock, $5,000.

The Electric Heat & Power Company, Chicago. Capital stock, $5,000. Incorporators: Charles B. Coffeer, Alvah S. Hopkins and Howard B. Cook.

The Warsaw Electric Company, Warsaw, Ind. Capital stock, $30,000. Incorporators: Noah J. Clodfelter, A. T. Spencer, Charles J. Lohman and J. C. Hamilton.

The Sutton-Steele Electrical Company, Dallas, Tex. Capital stock, $20,000. Incorporators: Walter L. Steele, Henry M. Sutton, Emmett A. Ellis and J. L. Sale.

The Bonham Electric Light & Power Company, Bonham, Tex. Capital stock, $25,000. Incorporators: J. F. Arledge, J. B. Russell, J. N. Rainey and E. F. White.

The Cass & Aaron Company, Chicago—to manufacture electrical machinery and supplies. Capital stock, $10,000. Incorporators: Rush S. Palsbury, Jacob Aaron and Philip Cass.

The Diamond Meter Company, Peoria, Ill.—to manufacture electric meters and other appliances. Capital stock, $30,000. Incorporators: E. H. Couch, W. E. Heyle, A. B. Fink and O. A. Scheefer.

The Higgins-Olmstead Company, Rochester, N. Y.—to manufacture and sell gas and electric fixtures. Capital stock, $10,000. Directors: Ezra M. Higgins, Morris Olmstead and J. Lansing Stewart, all of Rochester.

The Dayton & Xenia Traction Company, Dayton, O—to build and operate an interurban street railway between Dayton and Xenia. Capital stock, $300,000. Incorporators: J. M. Wilson, O. O. Ozias, F. D. Bittinger, Isaac G. Kennedy and Philip A. Kemper.

The Northern Development Company, Bangor, Me.—to produce, lease and sell electricity and other power for manufacturing and other purposes within the Indian townships Nos. 1 and 2 in Penobscot County, etc. Capital stock, $1,000,000; nothing paid in. President, Henry M. Prentiss of Bangor; treasurer, Charles W. Mullen of Oldtown; directors: Henry M. Prentiss and Charles W. Mullen.

Dayton & Eastern Traction Company, Dayton, O.—to operate an interurban electric railway. Capital stock, $10,000. Directors: Henry B. Pruden, George R. Wright, H. O. Cox, William A. Mays and W. S. McConnaughey.

The Perth Amboy Railroad Company, Perth Amboy, N. J. Capital stock, $30,000. Incorporators: Leonard Lewisohn, Adolph Lewisohn and Charles J. Witterberg of New York City; James T. McCoy, George J. Haney, William E. Tobey, O. P. Sells, Wesley J. Havel and Sidney Riddlestorffer of Perth Amboy.

The Tonawanda Cataract Power Company, Tonawanda, N. Y.—to distribute electricity for light, heat and power within the town of Wheatfield and city of North Tonawanda and the town and village of Tonawanda. Capital

stock, $100,000. Directors: Charles A. Sweet and Lincoln A. Grow, of Buffalo; Edward D. Adams, Francis Lynde Stetson, Edward A. Wickes and William B. Rankine, of New York City.

The Dundas Electric Company (Limited), Dundas, Can. —to supply steam, heat, electricity or natural gas for heat, light and power. Capital stock, $40,000. Some of the members of the company are George Hamilton Harper, Richard Todd Wilson, James John Grafton, Emilia Beatrice Harper and John Bertram, all of Dundas.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 25, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

612,875. Trolley-Stand. William T. Shryock, Allegheny, Pa. Filed July 20, 1897.

612,929. Insulator and Hanger for Electric Railways. Willie C. Keithey, San Francisco, Cal. Filed Jan. 26, 1898.

613,084. Underground Electric Railway. George W. Smith, St. Louis, Mo. Filed May 28, 1898.

613,175. Underground Electric Railway System. Fred D. Robb, Hot Springs, Ark. Filed July 2, 1897.

613,181. Trolley-Pole. John Walsh, Elyria, Ohio. Filed Nov. 2, 1896.

ELECTRIC LIGHTS AND APPLIANCES.

612,999. Electric-Lamp Guard. Herman M. Underwood, Chicago, Ill., assignor to Louis M. Cole, same place. Filed Aug. 19, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

612,943. Electric Furnace. Louis Bresson, Lyous, France. Filed Feb. 8, 1898.

612,977. Armature-Winding. Andrew L. Riker, New York City. Original application filed Nov. 19, 1897. Divided and this application filed April 18, 1898.

613,090. Apparatus for Producing Radiation of Electricity. Charles H. Stearn and Charles F. Topham, London, England; said Topham assignor to said Stearn. Filed Dec. 20, 1897.

613,116. Dynamo-Electric Machine or Motor. Sidney G. Brown, London, England. Filed April 9, 1898.

613,135. Alternating Current Electric Motor. Anthony S. Frazer, Tynemouth, England. Filed Dec. 28, 1897.

613,177. Safety Device for Suspended Conductors. Joseph N. Thomas, Johnstown, Pa., assignor to the Steel Motor Company, same place. Filed Jan. 20, 1898.

613,203. Alternating-Current-Motor System and Method of Operating Same. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Filed April 10, 1897.

613,204. Alternating Current Asynchronous Machine. Maurice Hutin and Maurice Leblanc, Paris, France, assignors to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Filed May 4, 1897.

613,205. Electric-Current Leveler. Maurice Hutin and Maurice Leblanc, Paris, France. Filed Dec. 16, 1897.

613,206. Method of and Means for Synchronizing. Maurice Hutin and Maurice Leblanc, Paris, France. Filed Dec. 30, 1897.

613,209. Alternating-Current Dynamo-Electric Machine. Maurice Leblanc, Paris, France, assignor to the Societe Anonyme pour la Transmission de la Force par l'Electricite, same place. Filed April 10, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

613,036. Telephone-Exchange System. Charles S. Heilman, Philadelphia, Pa., assignor, by direct and mesne assignments, of three-fourths to James S. Thompson, North Tonawanda, N. Y. Filed Nov. 21, 1896.

613,080. Telegraphy. Clarence D. Royse, Greencastle, and Walter A. Royse, Indianapolis, Ind., assignors to themselves and Mollie M. Royse, Indianapolis, Ind. Filed Aug. 11, 1897.

MISCELLANEOUS.

612,810. Railway Signal. William Andrews, London, England. Filed Dec. 20, 1897.

612,880. Electric Contact-Box. Joseph N. Thomas and William M. Brown, Johnstown, Pa., assignors to the Johnson Company of Ohio. Filed March 22, 1898.

612,885. Annunciator. Oscar Weiderhold, Summit, N. J. Filed Oct. 2, 1897.

613,054. Electric Fan. Daniel L. Bates and Russell H. Bates, Dayton, Ohio. Filed July 21, 1898.

613,062. Thermostat. Wilson E. Facer, Cleveland, Ohio, assignor of one-half to Charles H. Tucker, same place. Filed Nov. 4, 1897.

613,128. Electric Switch. William Ely, Providence, R. I. Filed Sept. 5, 1896.

613,129. Electric Switch. William Ely, Providence, and Walter B. Bernardini, Lakewood, R. I., assignors to the Hone Electric Appliance Company, Providence, R. I. Filed July 29, 1896.

TELEPHONE AND TELEGRAPH.

The Sine-Wave System of Telegraphy.

General Greely, Chief Signal Officer, in his annual report expresses his belief that the discoveries and inventions of Prof. A. C. Crehore and Lieut. Col. George O. Squier, which were fully explained in ELECTRICITY several months ago, have assumed such form and phase as to be of the greatest value to the commercial world. These discoveries outline the sine-wave system and have been tested extensively not only in this country but in England with satisfactory results. An abstract from General Greely's report says the first practical tests of the cable transmitter have just been made through the courtesy of George Clapperton and other officials of the Commercial Cable Company of New York. The experiments were made over the cable between New York City and Canso, which had a length of 827 knots and electrical resistance of 13,000 ohms, and an electric distributing capacity of 231 microfarads. These tests were made between September 25 and October 16, 1898.

The change from existing telegraphic methods consists in the substitution for the present appliance of a transmitter sending smooth waves, such as are obtained in alternating currents, working without making any other changes whatever in the elements of the present system. The conditions for the transmission of messages over long cables are distinctly and widely different from those on aerial lines. The necessity of increased speed over ocean cables, while not generally appreciated, is strikingly obvious when examined from a commercial standpoint. Since every cable spanning the Atlantic Ocean costs several million dollars, the value of any discovery that will increase the working power of these is at once apparent. General Greely has no hesitation in expressing his opinion that the sine-wave system, which also admits of easy duplexing, will within a year or two increase very materially the working capacity of every cable to which it is applied.

Advices from South Africa state that no sooner was the British flag floating over Omdurman than Mr. Cecil Rhodes at once took steps for expediting his scheme for a trans-African line of telegraph from Cape Town to Cairo. Mr. Rhodes's lieutenant, R. D. Mohun, has already left Bombay with an expedition, bound either for Zanzibar or Mombasa. The party will take advantage of the agreement lately come to between the promoters and the Congo Free State and will construct a telegraph line from Lake Tanganyika to Stanley Falls, on the Upper Congo, the work being carried out under the commission of the State. W. Cavendish, the well known explorer, is already carrying the line northward, through the extreme northern territory of the Chartered Company, and it is confidently expected that he will form a connection with the Mohun line within the next two years. By that time the Tanganyika line will have reached Stanley Falls, and Cape Town will be in telegraphic communication with the chief town on the Upper Congo, or, in other words, half the length of the line which is to connect Cape Town with Cairo will be complete. On the other hand, advices from Alexandria are that the line is being pushed southward as fast as possible. Kitchener kept up complete communication between the front and Cairo, and now the news comes that the line is being carried toward Fashoda from Khartoum at the rate of four miles a day.

The N. Y. *Commercial*, which has lately been giving a good deal of attention to telephone matters, intimates that it has knowledge of a proposed consolidation of the independent companies: It says: "There are about two thousand rivals of the Bell Telephone Company, so great has been the opposition to their system of extortion both in this and other cities. The reason that the existence of these rival companies has been unnoticed is that they have had their birth in the determination of opponents of extortion to establish local telephone services at a reasonable rate. They are scattered companies, lacking the alliance that gives a long distance wire. Since the incorporation of the People's Telephone Corporation there are indications that these scattered companies are to be consolidated, and if this result is brought about the elephant will find that he is no longer merely tormented by the attacks of a host of flies that a swish of the tail disperses, but by an enemy as big and powerful as himself. That the elephant is awakening to a knowledge of this danger the *Commercial* is in a position to know."

The Kansas City (Mo.) *Times* notices the arrival in that city of Charles J. Glidden of Lowell, Mass., the president of the Erie Telegraph & Telephone Company. Mr. Glidden is on a tour of inspection of the different telephone properties in the management of which he is interested. He is reported in the *Times* as saying: "The development in the telephone business throughout the country during 1898 will be far in excess of any previous year since the invention was placed upon the market by Prof. Bell. The companies, more particularly those operating in the thriving sections of the country west of New England, will increase their lists of subscribers from 10 to 25 per cent. The long distance telephone lines are reaching out to every important city and town in the country, and before the close of the century the Atlantic coast will exchange greetings with the far Pacific coast points, marvelous as it now seems. These lines now extend to thirty-three States and bring fully three-fourths of the population of the country within talking distance. The country is practically one immense telephone exchange."

A Mankato, Minn., dispatch dated October 20 says: "What is believed to be a telephone war was inaugurated to-day by the Northwestern Company offering free residence service to those having connections at their places of business. The new local company has its lines up and will be ready for business December 1. The Western Electric Company to-day connected with the Northwestern and removed its toll line from the Blue Earth Valley Company's office."

The long-distance telephone line connecting San Francisco with Portland, Ore., has been completed, and the mayors of the two cities have congratulated each other over the wire. Mayor Phelan of San Francisco sent the following message:

"San Francisco is much gratified to have been brought within direct speaking distance of the city of Portland. Such service will tend to draw us closer together and unify the interests of the Pacific Coast."

To this Mayor W. S. Mason of Portland responded:

"May the commercial relations be woven more closely since the means of communication are by this method a great advance over all previous facilities. May the cities of San Francisco and Portland ever occupy the position of leaders in all enterprises that will advance the interests of the Pacific Coast."

Arrangements have been completed for telephone communication between Armour, S. D., and points west and south. A line will be run to Greenwood, thirty miles south, and also to Edgerton and Wheeler, west on the Missouri river. These points in Charles Mix county are off the railroad and have no other communication with the outside world than by the slow stage mail routes.

The Tuscarawas Home Telephone Company, with headquarters at New Philadelphia, O., a new corporation, intends to operate a telephone system between New Philadelphia, Canal Dover, Uhrichsville, Dennison, Canton, Carrollton, Cadiz, Cambridge, Coshocton, Millersburg, Wooster and neighboring villages.

Henry C. Garber, solicitor for the Central Union Telephone Company, was indicted by the grand jury at Akron, O., recently on the charge of promising a bribe to City Commissioner Daniel McGorry. There were four counts in the indictment. Garber's home is at Greenville, O. He claims that the charges against him are false.

At a special stockholders' meeting of the New York & New Jersey Telephone Company, held in Brooklyn on the 27th ult., a unanimous vote was cast favoring the increase in capital stock from $5,000,000 to $8,000,000 proposed by the board of directors. There were 34,493 shares of stock represented out of a total of 46,624.

The city of Paducah, Ky., has sold to the highest bidders two telephone franchises. One was bought by the Kentucky Electric Company for $100, and the American Telephone Company bought the other. The company operating the present system did not bid.

The Duplex Telephone & Construction Company have asked for a franchise to operate a telephone system in Yonkers, N. Y., promising to give a satisfactory service for $3 a month.

The application of John Enoch for a 30 years' franchise to operate a telephone system in Kansas City, Mo., is being considered by the council.

New Companies Incorporated.

The Tuscarawas Home Telephone Company, New Philadelphia, O. Capital stock, $75,000. Directors: James S. Bailey, Jr., Frank W. Bainbridge, John W. Yeagley, O. S. Welty and J. H. Mitchell.

The Kenton Telephone Company, Kenton, O.—to operate a telephone system to Marysville, Bellefontaine, Wapakoneta and Lima. Capital stock, $30,000.

The Fire Alarm Telephone Signal Company, New York City. Capital stock, $100,000; amount paid in, $250. Incorporators: Thomas R. Brown, New York City; L. S. Filbert, John Lamon, Albert Goldstein and F. R. Shattuck, Philadelphia.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12⅜c.; Lake, 12½c.; casting, 12⅛@12¼c.

The Consolidated Traction Company of Pittsburg, Pa., has declared a dividend of $1.50 per share on its preferred stock, payable November 14.

The Coney Island & Brooklyn Railroad Company has declared a quarterly dividend of 2½ per cent. This is an increase in the rate of 2 per cent. per annum.

Beginning on November 1, the dividend rate on stock of the Metropolitan Street Railway Company of Kansas City, Mo., was increased from ½ to 1 per cent. quarterly.

The American District Telegraph Company of New York has declared a dividend of 1 per cent., payable November 15. Transfer books close November 7 and reopen on the 15th.

A dispatch from Columbus, O., states that the earnings of the Columbus Street Railway for the third week in October were $14,220.17, or $2,946.52 more than the earnings for the same time in 1897.

The Erie Telegraph & Telephone Company has declared its quarterly dividend, No. 60, of 1 per cent., payable November 21. Transfer books close November 12 and reopen November 21.

The gross earnings of the Brooklyn Rapid Transit Company for the year ended September 30 were $5,912,891; net earnings, $2,195,270; gross income, $2,438,151; surplus, $368 220.

A local financial paper states that the General Electric Company refused the Manhattan electrical equipment contract because of the demand for a security bond of three times the amount involved.

A charter has been granted by the Secretary of State of West Virginia to the Edison Junior Electric Light Company, with the privilege of increasing the capital stock from the amount subscribed ($100) to $500,000.

The Kings County and Brooklyn elevated roads are reported to have come to an agreement whereby the former will use the tracks over the Brooklyn Bridge for $83.33 a day, running half as many trains as the Brooklyn Company.

The directors of the New England Telephone Company have declared the regular quarterly dividend of $1.50 per share, payable November 15 to stock of record October 31. Transfer books will be reopened November 14.

The New York Stock Exchange has listed the $2,551,200 new preferred 7 per cent. cumulative stock of the General Electric Company, that being the total amount of the preferred stock as reduced to 60 per cent. of the original issue.

The stockholders of the West Roxbury & Roslindale Street Railway Company, West Roxbury, Mass., will increase the capital stock of $100,000 for the purpose of funding the floating indebtedness and extending the company's tracks.

Judge Badger has issued an order of foreclosure against the Columbus (O.) Central Street Railway, at the instance of the Cleveland Savings & Trust Company, which holds a mortgage for $1,500,000 on the property. G. W. Worthington of Cleveland will conduct the sale.

An additional $227,000 of first mortgage gold 5s of the Brooklyn Rapid Transit Company has been listed by the New York Stock Exchange, making the total amount listed to date $6,625,000. The Exchange has also listed $2,255,000 first consolidated mortgage gold 5s of the Brooklyn, Queens County & Suburban Railroad bearing the guarantee of the Brooklyn Heights Railroad Company.

Among the bills recently introduced in the councils at Philadelphia and referred to committees was one granting permission to the Standard Telephone & Telegraph Company to construct and operate a separate underground system. According to the bill, ninety days after its passage the company must submit its plans, and the work is to be completed in four years, and also a bond of $50,000 shall be filed.

The New York Stock Exchange authorized that $2,000,000 additional capital stock of the Third Avenue Railroad Company be added on November 2, 1898, to the amount already on the list, making a total of $12,000,000 of stock listed. The proceeds as stated are to be used for the purpose of providing funds to change the cable system to the underground electrical system upon the Third Avenue, 125th Street and Tenth Avenue lines. The new stock was offered to stockholders at par.

On the 28th ult., in Dubuque, Ia., Judge Shiras, of the U. S District Court, in the suit of the Old Colony Trust Company of Boston against the Dubuque Light & Traction Company, rendered a decision in favor of Doan & Co., former owners of the Eighth Street Railway, holding that the latter is entitled to recision of the contract by which the line was sold to the traction company. The suit was one of several involving property valued at half a million.

The Newport News and Old Point Comfort Railway & Electric Company on the 26th ult. closed a deal by purchasing the property of the Newport News, Hampton & Old Point Electric Railway Company. A mortgage was given to the Maryland Trust Company to secure $900,000 worth of 5 per cent. gold bonds. W. J. Payne of Richmond is president, and W. A. Post, general manager of the Newport News Shipbuilding & Dry Dock Company, is vice-president. M. E. Ingalls is one of the largest stockholders in the new company and his name appears as one of the directors.

The Illinois Supreme Court has decided that the city council of Chicago has the power to compel compensation for street railway franchises. The decision was given in the appeal of the Chicago General Railway Company against a judgment of $2,250 given the city in a suit to recover damages on the bond of the company. The ordinance granting the right of the company to operate a street car line imposed an annual license fee of $500 for every mile of track. The company protested against the payment of this fee. The Supreme Court upheld the right of the city to impose such a fee, and made the broader interpretation of the law that the city council could insist upon compensation for the use of the streets.

An investor in the securities of the Edison Electric Illuminating Company of New York is quoted as saying: "I am not at all disturbed by the rumors that the Metropolitan Company or the Third Avenue Company are going into the electric business. Even if they do the Edison Company can, in my opinion, maintain its position. The company is likely to have net earnings this year approximating $1,200,000. After deducting fixed charges there should be considerably more than $800,000 available for the stock, which will make a very handsome percentage of earnings."

The Denver "News" says: "The entire system of the Denver Tramway Company will be operated by electricity generated at the coal mines in the Lafayette district by early next spring. The officers of the Tramway Company deny this 'officially,' but steps are now under way for the formation of a company composed largely of Tramway and coal trust owners who will erect at the coal mines an immense steam plant which will furnish power for the generation of thousands of horse-power of electricity which will be brought to Denver and used on the company's lines. At various times within the past three months the fact has leaked out that there was to be a large power plant installed in the coal field, but only within the past few days has the matter taken definite shape, and so far along has the plan gone that it is a certainty that work will be commenced during the winter and the pole line completed by spring."

ELECTRICITY.

Vol. XV. NEW YORK, NOVEMBER 9, 1898. No. 18.

ELECTRICITY.

Published every Wednesday by the

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	2.00
Foreign Countries,	4.50
Single Copies,	10 cents

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Electric Street Railways of New York City. The cable as a method of propulsion for street railway cars in New York City is apparently doomed, and will shortly be superseded by electricity, just as horse-car lines were supplanted by the cable roads about four years ago. The general adoption of electricity as a motive power for the street railways of this city is undoubtedly a good thing so far as the comfort, convenience and safety of the citizens are concerned. Some three years ago the Metropolitan Street Railway Company built an electric conduit line along Lenox avenue, more as an experiment than anything else, all previous attempts at electric conduit traction both in this country and abroad, with but one exception, having proven dismal failures, and so skeptical was the company of obtaining satisfactory results from an engineering and financial standpoint that the line was built in a most substantial manner, supported on heavy iron yokes, thus enabling the road to be readily converted to a cable system if found advisable.

The very fact that the road was built in so substantial a manner contributed materially towards its successful operation, and the company was encouraged to introduce underground electric traction on its Madison, Amsterdam, Second and Eighth avenue lines as well as on its Fifty-ninth street line. At the present time the work of installing the underground trolley is being rapidly prosecuted along Sixth avenue, and already electric cars are in operation on that line as far down as Fourth street. Still more recently the necessary steps have been taken looking to the introduction of electric conduit traction along Broadway, the work of laying conduits for the feeder cables being pushed rapidly from both Fifty-ninth street and Bowling Green. About the only other change in the Broadway line which it will be necessary to make in order to convert it from cable to electric will be the placing of handholes in the conduit at intervals of fifteen feet to hold the insulator boxes.

The Third Avenue Railroad Company also has begun the work of changing its Third avenue cable line to an electric system and contemplates installing a similar system on its Boulevard line, which is at present operated by horses. With all these important changes either already begun or shortly to be undertaken, another year should see about the last of horse and cable traction in New York city. That the underground trolley system possesses many advantages over the cable is not to be doubted, as an electrically propelled car is at all times directly under the control of the motorman and may be run either forward or backward at will, whereas a vehicle drawn by cable cannot be driven backward, which is a decided disadvantage in crowded thoroughfares such as are frequent in this city. Another serious objection to cable traction is the fact that at times as many as several hundred cars are all depending on a power station engine to be kept in motion, and should any unforeseen accident occur, as frequently happens, requiring the shutting down of this engine, all the cars along the line are stalled. Furthermore, by the use of electrically operated cars there will be no opportunity of a grip's catching a loose strand of cable, resulting in collisions and other accidents. The principal reason, however, why the cable is being so rapidly discarded in behalf of electricity would seem to be owing to the fact that an electric conduit system has been found more economical to operate than any other system.

According to an article which recently appeared in the *Street Railway Journal* giving the relative cost of operation of cable, electric and horse railways in New York City, as determined by the Metropolitan Street Railway Company for a year, cable lines averaged 16.42 cents per car mile, horse lines 17.87 cents and electric lines 10.23 cents. This low cost of operation of electric lines per car mile may partially be accounted for in the greater speed made by electrically propelled cars and consequent reduction in cost of labor.

The public press has lately taken up the question of the braking of the new electric cars now in operation, claiming the devices now in use for quickly stopping a car are inadequate and are moreover responsible for a number of accidents which have recently occurred. Commenting on this subject, a recent issue of the New York *Herald* says:

"This brake does not vary in principle from, and to outward appearances is identical with, the familiar twisting brake that has been in use on horse cars for more than half a century. It served its purpose fairly well in stopping horse cars, but while the motorman is twisting his old fashioned brake his ponderous car plunges on with hardly a check to its speed. It would be about as reasonable to depend on the old hand brakes operated from the car platforms in response to the whistle for the control of the Empire State Express."

Although many improvements have been wrought in the old form of hand brake referred to in the above paragraph, this question of providing suitable mechanism for checking the speed of the long and heavy cars now coming into use will have to be taken up and dealt with most thoroughly. It would seem unquestionably true that the improvements in braking have scarcely kept pace with the increase in weight and length of cars, although

there are several electric brakes patented—in fact in actual use—which might be advantageously adopted by the Metropolitan Street Railway Company for controlling its cars.

* * *

A Long-Distance Transmission Plant.

The generating of electricity by means of water power to be transmitted at high voltage over long distances is by no means confined to California, Niagara and Switzerland. The city of Victoria, in British Columbia, is now lighted by electricity and has also an electric street railway in operation by means of power transmitted over a long stretch of wire. The work of conducting power for these purposes from what are known as the Sooke Mountains was completed during the month of August. Sixteen miles from Victoria the waters from what is claimed to be the highest fall in Canada, with an elevation of 2,300 feet above the sea, form a lake with an area of over one hundred acres into which empties Goldstream River. This river is tapped some three miles from its source to form an artificial lake or reservoir covering about seven acres. From this reservoir a steel pipe thirty-three inches in diameter and 6,700 feet in length has been laid, through which the water for operating the turbines passes. As the power station is at an elevation of but 460 feet above the sea a head of 1,000 feet is obtained.

The practically inexhaustible supply of water is regulated by automatic governors, ensuring steady action of the dynamos. In the power house, located at the foot of a mountain, is an electric plant said to be without a rival for size and completeness on the North Pacific Coast. From the power house the electric current is carried by six copper wires, twenty-one hundredths of an inch in diameter, twelve miles to the city, and furnishes power sufficient to operate not only the street car and electric lighting system, but factories as well.

* * *

Electricity in Japan.

Of all the nations of the world, Japan during the past quarter of a century has probably progressed more than any other. Fifty years ago that country ranked with China in conservatism, adhering to antiquated methods and customs which had been in vogue practically without change for centuries. Machinery, in the modern sense of the word, as an aid to labor was unknown, everything in the industrial line being done by hand. Western ideas and improvements were most carefully excluded, it being generally thought that any innovations would be immediately followed by ruin.

In 1854, however, after repeated efforts, Japan was opened up for the first time to Western commerce through the medium of a treaty brought about by Commodore Perry. This caused an internal revolution which was the means of preventing the introduction of any degree of civilization into Japan until 1870. Dating from this period, however, Japan has not been slow to avail itself of modern methods, and in no line is this more conspicuous today than in that pertaining to electricity. The principal cities throughout the Japanese Empire are in direct communication one with another by means of numerous and well-equipped telegraphic lines, while in some of the larger cities such as Tokio and Yokohama telephones abound. As an illuminant electricity is also rapidly becoming popular. Tokio, the capital of the empire, occupying an area of 100 square miles and having a population of about 1,400,000 inhabitants, has been lighted by electricity for a number of years and now has a most complete and up-to-date lighting plant. The latter is equipped with ten triple expansion condensing engines, which operate a number of single-phase and three-phase generators wound for 2,000 and 3,500 volts respectively. In the thickly settled portion of the city current for lighting is distributed by means of the Edison three-wire system from sub-stations where induction motors have been installed.

In the matter of electrical street railways Japan would seem not so well off as in lighting. There are at the present time but about 60 miles of street railways all told in the empire, of which but two lines, those of Kyoto and Nagoyo, are operated by electricity. A number of other electric roads are said to have been projected in different cities and towns throughout that country, none of them however having as yet materialized. For that matter the hesitancy shown by Japan regarding the introduction of the trolley has until very recently been exhibited by several supposedly much more enlightened nations in Europe. If the rumor which is at present afloat is to be credited, the near future should find Japan a network of electric street railways. According to the public press the Japanese Government has recently made a proposition to a well-known electrical concern in this country, looking towards the installation and operation of electric street railway lines and lighting plants in all parts of that empire. With this object in view a syndicate is now being formed, so it is alleged, with a capital of $10,000,000 to prosecute the work. Whether this proves to be the case or not, one thing may be depended on, and that is that in the near future the Mikado's realm will be amply provided in one way or another with up-to-date methods of transportation.

Under the Searchlight.

Notes and Comments on Various Topics.

SOME of the methods introduced in the tunnel boring for the Jungfrau Railroad in Switzerland, in order to meet the exigencies peculiar to the extreme winter weather, are of special interest to engineers. On this work blasting gelatine is used, an explosive which freezes at about 40° Fahr., and, in its frozen condition, is very dangerous to handle, being unlike dynamite in this respect. It seems that the contractors who are blasting out the Jungfrau tunnel keep their explosive in a sort of safe heated by electricity, so that any danger of the gelatine freezing is entirely obviated. Dynamite, or some other derivative of nitro-glycerine, is in very common use for blasting and other purposes, and is commonly frozen for safety. It is usual to thaw it out before it is used, but frequent accidents thus occur, and it is thought that a dynamite thawer operated by electricity would be alike safe and convenient.

* * *

THE fair telephone operators in New York City probably do not appreciate what similar operators in other countries have to endure for even less wages. In Vienna, for instance, the telephone girls are required on arriving at the exchange in the morning to change their dresses and wear a uniform while on duty. This precaution is thought necessary as the dust brought in from the street might affect the instruments. The costume consists of a dark skirt and waist with sleeves striped black and yellow—in other words, the Austrian national colors. Imagine telephone girls in this country having to put on the attire of the Goddess of Liberty!

* * *

MR. WILLIAM A. EDDY in a report to General Greely on the results of his kite experiment near the Statue of Liberty says: "Electrical tests of the absorbing power of the statue were made on November 1, 3 and 4. A Leyden jar was used on the last test, and reaffirmed the first discovery that the statue does not influence the air much beyond one hundred feet in a horizontal direction from the statue nor much more than twelve hundred feet in a perpendicular direction above the torch. During the experiment four kites were driven into the water and destroyed."

* * *

WHAT is known as the Wilde prize of 40,000 francs has recently been awarded by the French Academy to Mr. Charles A. Schott, of the United States Coast and Geodetic Survey, for his excellent work in territorial magnetism, and chiefly for the theoretical investigations for determining the variations of magnetic elements. This is the first time the prize has been awarded, and that it should go to an American is decidedly flattering.

* * *

AN electrical beefsteak party was held a few days ago in a restaurant in New York. Prof. G. B. Cary, a French scientist with a gastronomical bent, had invented an electrical grill and brought it to the place to be tested. A few experts in electricity were bidden to the tests. These included editors of electrical publications, electrical engineers and ordinary consumers of electricity on telephone and similar circuits. Steaks and chickens were put between the heating surfaces, and the guests waited for eight minutes for the steaks to cook and thirteen minutes for the chickens, drinking the health of the inventor meanwhile. The new device did its work well so far as the cooking was concerned, but the meats appeared as if they had been baked instead of broiled, and lacked the tempting brown exterior produced by coal or gas heat.

* * *

WHEN Thomas A. Edison's second daughter was born, says the New York *World*, his technical assistants in the laboratory at Orange presented him with plans for a cradle intended to save Mrs. Edison much of the worry and trouble usually experienced by mothers. Several other ideas were submitted to the committee, but the thought of the Wizard ambling up and down the room in the dead of night, occasionally stepping on a semi-submerged tack, was too much for them, so the cradle was decided on. It was called the "automatic electric baby tender." It was an ordinary cradle with ingenious devices for the child's comfort attached. Immediately above the spot where the baby's head would lie was a diaphragm, somewhat like a telephone receiver. If the infant should start crying, at the very first wail communication was established between the diaphragm and an electric clock. At the same time the cradle was set rocking by means of a small motor. If the remonstrance continued beyond a certain time the clock released a lever and an arm attached to the side of the cradle (operated by what is called a bell crank lever), carrying a nursing bottle, was swung over the baby's mouth. If hunger was not the trouble and the wails continued, another arm on the opposite side swung over the child's mouth with paregoric. At the same time the electric current was turned into a set of magnets placed around the cradle, and any pin which might be causing the trouble would be at once removed. If the yells continued, the "thirty-third degree" was applied. Two arms, lying flat in the cradle under the baby, were slowly raised and the child turned over. Then an electric spanker fastened to the footboard proceeded to do its work with neatness and despatch. However, Mr. Edison persists in regarding the baby's joy electric cradle as a joke.

* * *

IT would seem as though a trolley car could be adapted to many uses. A grand stand at the Northwest ball park in Chicago was recently demolished by a mob of men, women and children by the aid of the trolley. The crowd secured a car and attached one end of a rope to a post supporting the roof of the grand stand, while the other end was tied to the car. When all was ready the trolley was started and the big roof fell in with a crash.

ELECTRICAL EQUIPMENT OF A MODEL PRINTING ESTABLISHMENT.*

BY GEORGE A. DAMON.

To even a casual observer the part which electricity is playing in industrial movements is an interesting study. The concentration of great manufacturing establishments about water powers and the opening up of vast suburban districts about our cities by means of the rapidly moving electric car, are every-day instances of the influence of electrical development upon constantly changing industrial conditions. Perhaps less evident, but none the less important, are the changes which are being brought about by the use of the electric motor in the operation of manufacturing establishments. Enterprising manufacturers have not been slow in appreciating the advantages to be gained by the electrical operation of their factories, and we have many instances where the cost of labor and of power has been reduced, or the efficiency of a process has been increased by the use of the electric motor.

There are few instances, however, where the adoption of electric power has led to such a radical departure from ordinary methods, or where greater advantage has been taken of the possibilities of electrical operation, than in the model printing establishment of the W. B. Conkey Company at Hammond, Ind. This great establishment is the result of more than 20 years' development. Starting with a small capital, Mr. Conkey gradually increased the size of his establishment until, about a year ago, it occupied the seven-story Franklin building on Dearborn street, Chicago, and two seven-story structures on Plymouth place, besides a large warehouse on Market street. While quite as successful as many other publishing houses, the operation of this immense plant in the center of a great city presented many disadvantages. Taxes were necessarily high, insurance rates oppressive and the cartage of raw material and finished product to and from the depots through a congested business district was slow and expensive, while its movement by the railroads was unsatisfactory. The mill construction of the buildings, their location with respect to surrounding structures and the extent of floor space employed made it necessary to supply artificial illumination to many parts of the factory during the entire period of operation. The relative location of the buildings made it necessary to maintain two distinct plants for power, heat and light. Power was transmitted from the engine flywheel to the various machines by means of belts, rope drives and pulleys. By actual tests fully 45 per cent. of the power delivered by the engine to the main driving shaft at average load was used to run the shafting, and this transmission loss was, of course, much larger at lighter loads.

A consideration of these disadvantages led the company to seek a new location with more advantageous conditions. A flattering bonus offer from Hammond, Ind., made it possible to secure a factory site with ample room and shipping facilities, and as a result the most extensive buildings for the purpose in the country have been erected and equipped there. Hammond is practically a suburb of Chicago, being connected to it by an electric road and six lines of steam railways. The belt line makes direct connection with fourteen trunk lines centering in Chicago. A special car leaving Chicago every night delivers small local freight upon the shipping platform of the plant at Hammond every morning. With the same freight rates as formerly, it has been found that the cost and time of handling shipments have been materially reduced in the new location.

The plant is located on a stretch of rolling prairie land and the buildings cover about four acres of ground space. A macadamized roadway extends along two sides of the main buildings, while an extensive park, containing artificial lakes, rare shrubbery and artistic flower beds, has been laid out before the main entrance. Hundreds of employes spend their noon hour upon the big playgrounds which surround the factory or wander in the woodland near at hand. But the most unique feature of the plant is the construction of the building. It extends over an area of 520 feet by 450 feet and consists of but one floor. This makes it possible to pay especial attention to the lighting, and as a result the whole roof resembles a vast skylight. The windows of the roof are glazed with frosted glass and are placed at an angle looking toward the north. Every 29 feet of roof space provides 11 feet of light. Owing to the angle of the roof the direct rays of the sun are kept out of the building, which is thus lighted by the soft-reflected rays from the northern sky. It would be hard to conceive of a more evenly or more thoroughly lighted factory building. The entire roof is built up of light structural steelwork resting upon cast-iron columns spaced on 29-foot centers one way and 16-foot centers in the other direction. The height of the trusses above the floor is 12 feet.

The general plan of the plant is shown by Fig. 1. The general and private offices, with the employes' dining, bicycle and wash rooms, are located at the front of the building. The press room occupies a space 116 by 212 in the center of the large structure. The receiving room and shipping room are conveniently located in relation to the side track platform, while the plate vault, electrotype room, composing room, store room and hard and soft bindery surround the central press room. It will thus be seen that the stock passes through the plant with a minimum amount of travel from the receiving platform to the shipping room. As everything is upon the ground floor no elevators are required. The power plant, with its boiler, engine and fan room, is located on the north side of the building convenient to the railroad tracks. Coal is delivered from the cars directly into bins in the boiler room.

The boilers are of the horizontal water-tube type with 3,472 square feet of heating surface and 60 square feet of grate surface per boiler. At the present time two boilers are installed, and the stack is situated so as eventually to be flanked on either side by two boilers of the completed battery of four. The breeching from the boilers to the stack is of sheet steel.

The stack is a self-supporting steel chimney 125 feet high and 54 inches diameter inside the gas flue. The courses for the first 30 feet from the top are made of three-sixteenths-inch plate, for the next 30 feet of one-fourth-inch plate, for the following 40 feet of five-sixteenths-inch plate, while the 25 feet coned base is made of three-eighths-inch plate. The stack is held in place by eight $1\frac{7}{8}$ inch bolts bedded in a foundation of concrete. A unique feature of the stack is the method used of inverting each section so that the top end of each section rests outside the section immediately above it. This prevents the soot washing through the joints and down the outside of the stack, as is too frequently the case with steel chimneys.

BION J. ARNOLD.

Consulting Engineer of the W. B. Conkey Company's Model Printing Establishment.

The engine upon the left end of the row of generating machinery is an $11\frac{1}{2}$ inch by 18-inch by 36-inch tandem compound non-condensing Corliss engine and runs at 125 revolutions per minute. This speed is rather high for a Corliss engine, but indicates the tendency of modern practice where the engine is directly connected to a generator. When properly designed there seems to be little reason why an engine with independent valves should not be run at this speed, and if successful at this number of revolutions per minute, we probably will not be satisfied until the speed is again raised. As long as the cost of electric generators of a given size increases in proportion as their speed is decreased, there will be great pressure brought to bear upon engine builders to produce a successful engine of the Corliss or similar type running faster than the ordinary 80 to 100 revolutions per minute. For purposes of power plants of this character the Corliss type of engine, in the minds of a great many engineers and purchasers, has advantages of economy in steam consumption and low cost of maintenance which engines of the high-speed type do not possess. The objection when directly connected to a generator is the cost of the unit.

This engine is fitted with double eccentrics and governors on both cylinders, the governor being of

* Read before the Chicago Electrical Association, November 4, 1898.

the Porter type. The special design of the double-ported admission valves permits a quick cut off, while the operation of the steam and exhaust valves by separate eccentrics gives the engine a long range of cut off and a large reserve capacity for overloads. The flywheel is made in halves, weighs 16,000 pounds and is 12 feet in diameter, giving a peripheral speed of 4,700 feet per minute. With 120 pounds initial steam pressure and a back pressure of three pounds the engine is rated at 160 indicated horse power and is guaranteed to develop each indicated horse power hour on a consumption of 21 pounds of steam. It

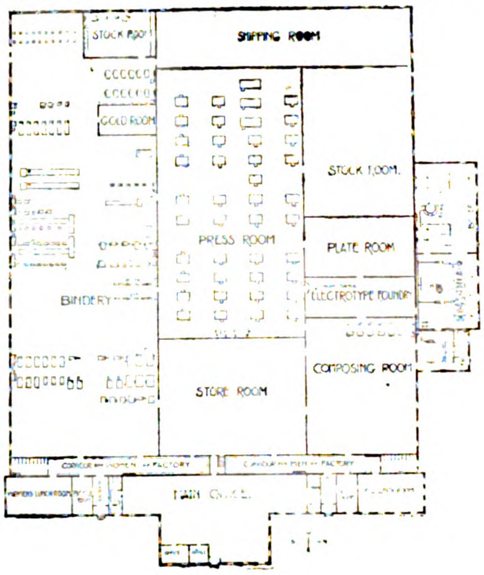

FIG. 1.

has an economical range of power between 100 indicated horse power and 225 indicated horse power, but is designed in all its parts to operate continuously on an overload of 100 per cent., or at 320 indicated horse power. Provision has been made in the piping to secure this overload by admitting high-pressure steam to the low-pressure cylinder. The conditions under which it may be expected to operate in this manner and at this unusual overload will be referred to later. The shaft of the engine is of open-hearth forged annealed steel. It projects through the outboard bearing a sufficient distance to carry a flange forged solid on the end of the shaft. This flange is to carry a coupling which connects the engine shaft to the generator shaft. Between the high and low pressure cylinders and in a pit beneath the floor of the engine room is a receiver fitted with reheating coils and provided with the necessary traps for returning the condensed water to the boiler.

The generators are compound wound and are designed to deliver 100 kilowatts output at 225 volts when running at 125 revolutions per minute. The field frame is split through the center on a horizontal plane, so that the upper part can be removed. This operation will not be necessary, however, in case repairs are required on the armature windings or field coils, as provision has been made to slide the entire armature frame parallel to the shaft, along cast-iron footings, a sufficient distance to clear the armature. The armature is of the iron-clad type, with a commutator of ample proportions. The brushes are of carbon and the brushholders are carried in a circular iron frame arranged to be moved by means of a threaded rod and a hand wheel, so that the position of the brushes may be adjusted. The field frame has eight poles and the compounding coils are provided with an adjustable shunt, so that the over-compounding may be adjusted over a range of from one to five per cent.

The arrangement of the machinery in the power plant is shown in Fig. 1. It will be seen that this plan calls for two engines and three generators. The second engine is also a tandem compound, non-condensing engine, but is of the center-crank type with overhanging flywheels. This engine is of twice the horse power of the side-crank engine; that is, it can develop sufficient power to operate economically two of the 100-kilowatt generators, though when necessary it will be able to operate all three of the generators.

The whole line of machinery is connected on the "Arnold system" of power-station construction. In this system each generator armature is mounted in such a way as to be perfectly independent of the remaining machinery, and by means of a suitable coupling can be put in operation or thrown out of service at will. The shaft upon which each generator armature is mounted is made hollow, so as to allow a solid shaft to be carried through it. This solid shaft is supported in two independent bearings near its middle and extends from engine to engine, but under normal operating conditions it is independent of the engines and of the generator shafts and lies idle in its bearings. Each end of this shaft is provided with a suitable coupling, so that it can be operated by either engine or by both working in unison. The result of this ingenious arrangement of shaft, hollow quills, bearings and couplings is that each generator can be operated by more than one engine. In a plant arranged with direct-connected units this feature is a decided additional advantage, for the units can be operated in much the same manner as in a belted plant. Ordinarily in a direct-connected plant the crippling of a generator will shut down its driving engine, or if an engine breaks down its contiguous generator must necessarily be taken out of service. The Arnold system obviates this disadvantage, and the result is that reliability is secured in the operation of the plant with much less reserve machinery than is ordinarily required. The arrangement may look complicated, but in reality it is simple, and for the advantages it secures it is comparatively inexpensive.

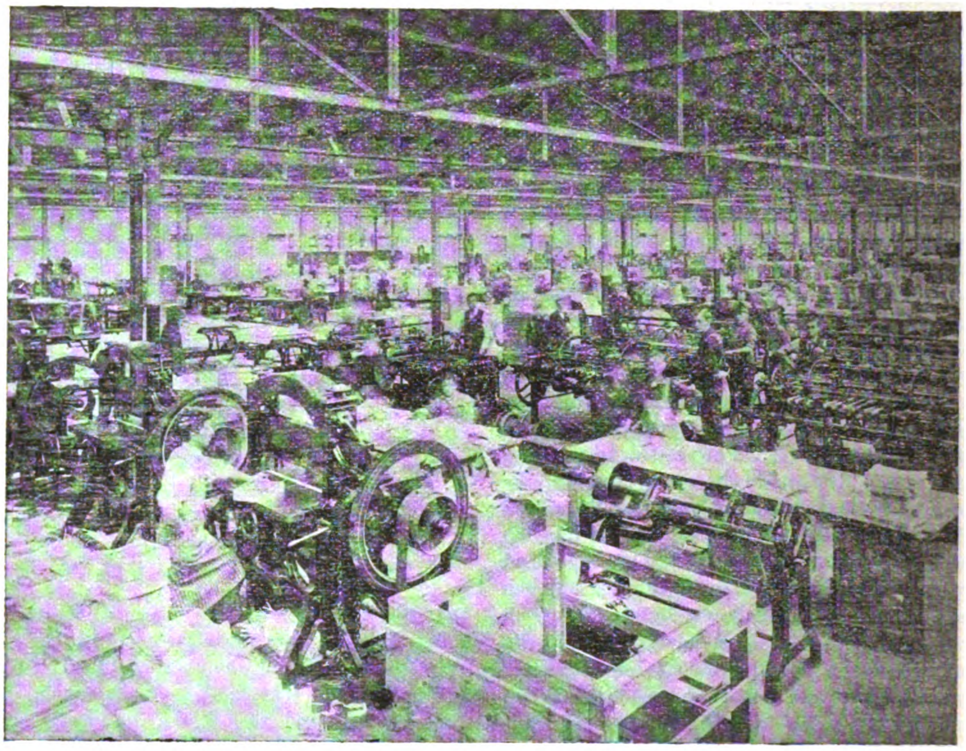

FIG 2.

The method which has been adopted to provide for an increasing demand for power in this plant may prove of interest. At the present time engine No. 1 and generator No. 1 have been installed and are now handling the load. A smaller 50-kilowatt high-speed unit is being placed in position for the purpose of carrying the load when the press room is working all right. It may also be used to furnish current for the lighting circuits when the combined power and lighting load becomes too large for the Corliss engine and 100-kilowatt unit. Eventually as the load is increased in size, engine No. 2 and the two additional generators will be installed, and the plant will then be ready to furnish economically all demands for power over a range of from 75 horse power to 525 horse power. It will be capable of handling a load of 400 horse power, with a reserve unit for operation in case of accident. For instance, if the larger engine should get out of order the smaller engine could be connected to both generators No. 1 and No. 2. The provision for admitting high-pressure steam into the low-pressure cylinder and the capability of the engine for standing an overload have already been mentioned. By taking advantage of these arrangements the smaller Corliss engine can be made to double its rated horse power and carry the load of the larger engine. To secure the same reliability and wide range of economical operation with an ordinary direct-connected plant would require four separate engine units, which would not only be more expensive in first cost, but would require larger foundations, greater floor space and more piping, as well as demand a larger amount of attention in operation.

The engine and generator foundation consists of a solid monolith of concrete eight feet deep and of sufficient width to give ample footing for the machinery. Water-tight iron pipes run through this foundation and under the cement floor of the engine room to the back of the switchboard for the purpose of carrying the generator leads. These leads consist of stranded rubber-covered and braided lead-encased cables of 600,000 circular mils cross section area.

The switchboard is of highly polished black enameled slate, $1\frac{1}{2}$ inches in thickness, with the usual indicating and regulating instruments. Separate omnibus bars are provided for the power circuits and the lighting circuits. Each generator is furnished with two main switches, by means of which it may be operated on either the light or the power circuits, or upon both at the same time.

Each feeder leaving the board passes through a fuse, the fuses being fastened in a row upon a special fuse block at the top and back of the board. From this block the feeders pass directly through the wall of the engine room into the factory. The power and lighting distributing system throughout the plant are independent of one another. In the factory two main distributing centers are located in a central position, one on the north wall of the bindery and the other on the north wall of the press room. The centers consist of small switchboards fastened to the side of the wall and surrounded with a hardwood asbestos-lined cabinet. Their main bus-

bars are connected back to the switchboard by means of large feeder cables. At each center a separate cabinet is provided for the lights and power, the various circuits leading to the different parts of the building leaving the distributing board through suitable switches and fuses. The main feeders are carried along the wall of the electrotype foundry to the press room. From here they are carried on the under side of the iron roof truss by being supported on porcelain insulators fastened to iron beams, which are firmly bolted up against the angle iron of the roof. The distributing circuits are carried upon porcelain insulators attached directly to the under side of the wooden roof beams and above the iron trusses. All the feeders and mains are thus installed in the "open work" style of construction. A workmanlike job has been done, however, and the wiring presents a very neat appearance.

The leads to the various motors and the wires to the arc lamps and switches are carried in iron-armored insulated conduit. In the case of a press motor, for instance, a porcelain cutout in a suitable box is placed at the top of an iron column 12 feet from the floor. From the bottom of this cutout box a single run of conduit is led down the side of the column, and thence along a groove in the floor to the motor. All the wiring about the presses, between the main switch, the controller and the motor is carried in iron conduit in such a way as to be thoroughly protected from mechanical injury.

The lighting of the plant is accomplished by means of constant-potential enclosed arc lamps. Experience has shown that a very satisfactory illumination

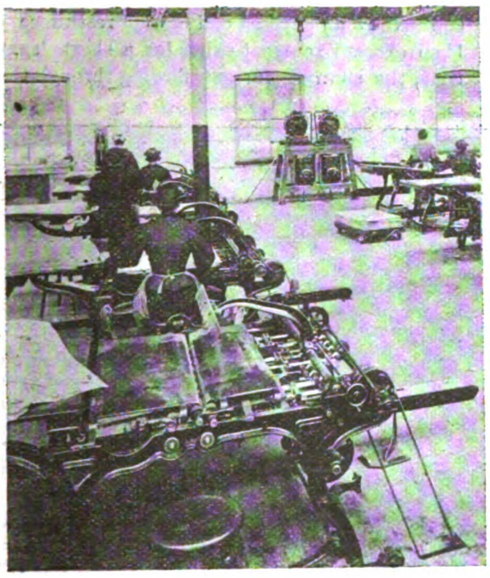

FIG. 3.

can be obtained by hanging a lamp in the middle of each bay and from every other roof truss. This makes each lamp supply light to a floor space 29 by 32 feet. When better illumination is required for any special work, incandescent drop lights are placed, and sometimes, as upon the presses, portable incandescent lamps with an allowance of cord are provided for work requiring occasionally a temporary light.

The arc lamps are controlled by double-pole, 220-volt snap switches carried on slate bases securely attached to the side of the iron columns. The wiring to and from the switches and to the arc lamps is run in iron-armored conduit fastened to the columns and to the under side of the roof trusses. At every lamp opening the conduit contains a tee looking down, and to this tee is screwed a short nipple carrying a hook upon which the lamp is hung. By this method of installation the wires are entirely concealed. Each set of four lamps is protected by a cutout placed in a manner similar to the ones protecting the motor leads.

There are installed in the plant at the present time a total of 95 motors, distributed as follows:

	H. P.
Electrotype Foundry.	
17 individual motors, belted or geared to dovetailing machine, trimmers, planers, roughers, saws, routers, black leaders, molding machines, beveling machines, blowers and jig saws	21
1 direct-connected to electroplating dynamo.	10
Bindery.	
15 belted to shafting, driving folders, book-covering machines, trimmers, sewers, wire-stitchers, sewing machines, case makers, embossers, rounding and backing machines	52
2 direct-connected to shafting, driving cutters and smashers	10
8 individual motors belted to knife grinders, tying machines and gluing machines	18 5
Stock Room.	
2 belted to shafting driving cutting machines, rotary board cutters, grinding machines, sizing machines and bevelers	6
Heating Apparatus.	
1 belted to blower fan to heat office	12
Machine Shop.	
1 belted to line-shaft driving machine tools.	10
Composing Room.	
1 belted to shaft driving typesetting and distributing machines	3
Press Room.	
6 belted to job presses, ink grinders and bronzing machines	5.5
41 directly attached to presses	173
Total horse-power of motors installed	321

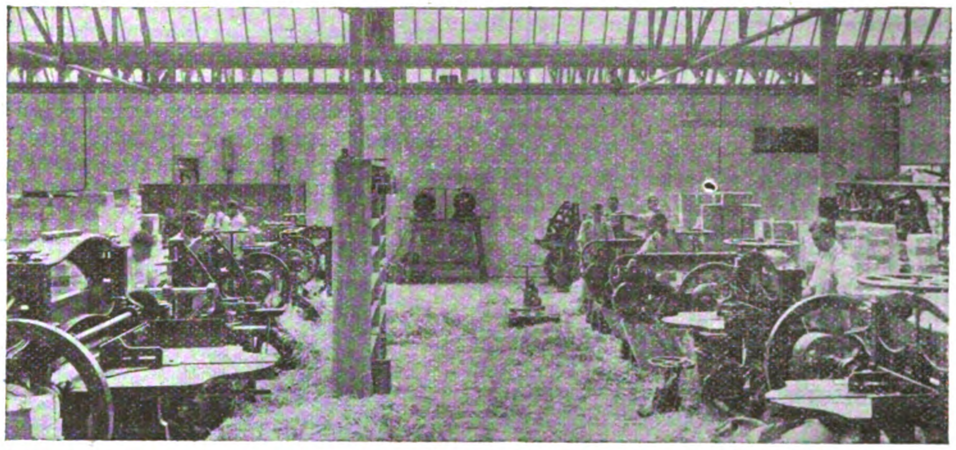

FIG. 4.

The motors throughout are of the Lundell type. This motor is made with one field coil, which is entirely protected by the form of the field casting. The armature is of the ironclad type with removable form-wound coils. The motors have a steady neutral point of commutation and do not spark under sudden changes of load.

The motors directly attached to the presses and shafting are multipolar, narrow in width, with a relatively large circumference of field frames. The commutator, like the armature, is narrow and of large diameter, with a large number of bars.

There are various considerations which usually determine in each case whether a motor should be belted, geared or directly attached to a machine, or perhaps indicate that the machine should be grouped with others of its class and driven from a common shaft. For instance, there are certain classes of machinery, such as folders, stitchers, type-setting and type-distributing machines, etc., which take but a very small amount of power, which are each in operation almost continuously and which can be arranged in rows convenient to a line-shaft. There are few if any advantages to be gained by driving such machines with individual motors, and especially is this the case when the driving shaft can be placed below the floor, as is done in the plant under consideration. Fig. 2 shows a number of groups of this class of machinery. The machine belts pass directly down through the floor to pulleys carried upon a shaft supported by floor stands bolted to planks in the bottom of the shaft pit. This pit is built with a concrete bottom and brick side walls, and is covered with the floor built in sections, so that it can be removed for purposes of inspection and oiling. The shaft is driven by a belted motor set upon a stand at the wall end. This motor rack is made of three by three timber, securely bolted together, and fastened to the floor. Underneath the motor and between the legs of the rack is placed the starting box. This box is mounted on a slate base, which also contains the main-line switch and the fuses for the protection of the motor. Each box is also provided with an overload attachment which will break the circuit in case of an excessive current. As a rule the motors belted to a line-shaft in this way are shunt wound and run at a speed of 1,000 revolutions per minute. Typical arrangements of this character are shown in Fig. 3.

It may seem strange, in view of the admitted losses in line shafting, that any shafting whatever was allowed in the plant, but when the inefficiency of very small motors and their comparatively large cost of installation are considered, reasons will not be found lacking for putting a limit on the tendency toward individual machine driving. In some cases, such as paper cutters, smashers or embossing machines, which depend largely upon the inertia of their moving parts to furnish the power for their operation, a great advantage is gained by having a number belted to a line-shaft, and thus operated by a common source of power, for under such conditions each machine gets the benefit of the stored momentum of the flywheels of the entire line. A case in point is shown in Fig. 4 which illustrates a row of cutters. Here are six cutters and a book-binding machine operated by one five-horse-power motor. Individual driving would have required at least seven one-horse-power motors, and the result would have been far from as satisfactory or economical. On the other hand, there are machines which may take a small amount of power, but which are in operation only intermittently, or perhaps cannot be conveniently located in positions to be belted to a line shaft. Such instances are found in the electrotype foundry, where there are numerous small machines, each with its individual motor either belted or attached by gearing.

The method of driving the large presses, however, presents the most problems. Here the conditions of operation leave but little doubt that individual motors should be provided. But whether to belt, gear or direct connect the motor to the press is the problem. The belted equipment is the cheapest, the easiest to buy and install, and the more convenient to repair, as an injured motor can be quickly replaced. The higher speed at which they run furnishes a certain amount of inertia to carry the press over the "centers" of each impression. The belted motor takes up valuable room, however, and as it must be protected it usually presents an unsightly appearance. The geared motor can be installed in most cases and is an improvement over the belted type, though the increased cost of its installation makes its advantage a doubtful one. The directly

connected motor takes the place occupied by the driving pulleys of a belt-driven press, and thus has the advantages of neatness and compactness. As presses are usually built, the main driving shaft makes five revolutions to every impression, so that a press operating at 1,440 impressions per hour requires a direct-connected motor running at 120 turns per minute. This slow speed means a large and comparatively expensive motor. Its armature must be keyed directly to the press shaft, and this often means that the shaft of the old press must be taken out to have an extension welded upon it. The slow speed of the armature prevents the accumulation of energy to help the press over the centers. In spite of these disadvantages, however, the improvement in the mechanical design of the equipment with direct-connected motors over the belted or geared arrangements, and the longer life of the slower running motors were thought to be sufficient to justify the extra investment, and therefore motors directly connected to the 41 presses were installed.

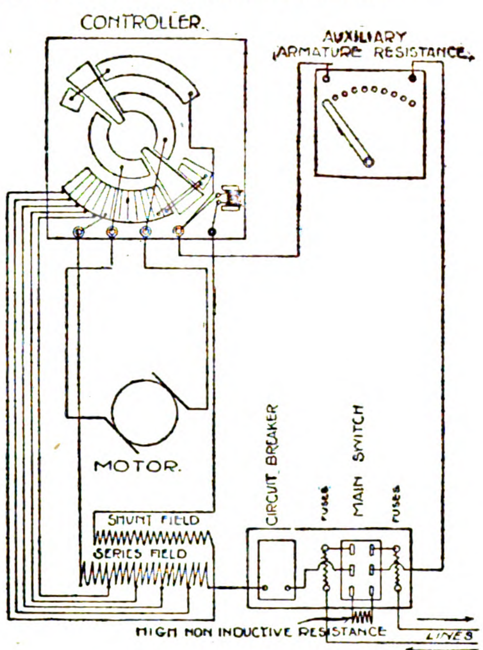

FIG. 5.

The control of the press motors presents a number of difficulties, and the solution which has been worked out in this case may prove of interest. A printing press controller should have a handle placed within easy reach of the feeder, by means of which the press can be conveniently started and stopped. In case of a failure of the current from any cause, the controller should be automatically released so as to return to the "off" position. It should have a locking attachment so that the pressroom foreman can adjust the press for a certain number of impressions per hour and then leave its operation to the feeder. This locking device should not interfere with the stopping or starting of the press, but should insure that while the press is in operation it will be running at the predetermined speed. With ordinary electric press controllers the convenience with which the feeder can change the speed of his motor is a temptation to "soldier" when not working directly under the eye of the foreman. The controller should provide for at least two back-up speeds and should have a handle on the side of the press opposite the feeder, by means of which the press can be run slowly in either direction in "making ready" operations.

The most important requirement, however, is to secure a wide range of speeds for the press. For instance, it is sometimes desirable to be able to operate a press at a number of speeds ranging between 1,000 and 2,000 impressions per hour. This means that the motor should be controlled between 84 revolutions per minute and 168 revolutions per minute, or that its lowest speed should be 50 per cent. of its highest speed. Now, the speed of an electric motor may be varied in three different ways: (1) resistance may be inserted in series with the armature, (2) the intensity of the field magnetism may be changed, or (3) the external potential applied to the motor may be altered. The first method is uneconomical and unsatisfactory in operation, as it results in an unsteady speed under such a variable load as is given on a printing press. The second method, while more economical than the first is limited in its application, for the speed of a motor cannot be satisfactorily controlled in this manner beyond the limits of about three-quarters of its full speed. To extend this range of speed and insure sparkless operation at the higher limits when the field is weakened, a large and expensive motor will be required. The third method requires complicated generating machinery and distributing circuits, and if but two voltages are used (one double the other) the system will not secure the range of speed desired.

The system of control adopted for this plant combines the first two methods. Between full speed and 75 per cent. of full speed the speed variations are secured by changing the field magnetism. This is accomplished by cutting in or out sections of the series field winding. Between three-quarters speed and one-half speed the various steps are secured by inserting resistance in the armature circuit. Three-quarters speed is taken as the average or normal speed of the press, and at this point all series field coils are cut out, and the motor is operated as a straight shunt machine with no resistance in series with its armature. In this way the main controller provides for ten variations in speed, five of which are secured by armature resistance and five by field commutation. An auxiliary resistance box is placed on the motor or adjusting side of the press, by means of which 10 additional speeds can be obtained between any two of the main controller speeds, so that this method of control secures 100 different speeds, and it is, therefore, possible to operate the press with a fine adjustment and always at the highest rate which the character of the work will permit.

The diagram of the controller connections is shown in Fig. 5; a steel rod passing down from the handle at the left of the press feeder, Fig. 6, operates the contact arms by means of a bevel gear. These arms carry carbon brushes, and, passing over the segments, cut in or out armature resistance and series field windings. The contact arms are held in a semi-circular cast-iron connection which contains a series of small holes corresponding to the number of speeds secured by the controller. Pivoted at the center is a movable arm fitted with a handle and pin which can be made to enter any one of the ten holes. When the current is turned on and the controller revolved, this arm moves around until it engages a pawl operated by an electromagnet. As long as the current is passing through the motor this magnet holds the controller in position, but it will release the arm as soon as the current is interrupted, and a strong spiral spring on the controller rod immediately brings the arm back to the "off" point. The "automatic" device is thus secured, while the locking feature is obtained by means of the movable arm, which can be set at any hole corresponding to any desired speed. The hole corresponding to the normal speed is marked and the press is usually operated on this point.

On the right of the feeder is placed a small panel board containing the main line switch, a circuit breaker and fuses for protecting the motor. The switch is of the "tumbler" type and is connected so that when thrown up it connects the motor ready for operation. When this switch is opened an extension of each blade makes a contact with the lower clips so as to short-circuit the shunt fields of the motor through a non-inductive resistance, providing a path for the field discharge and thus avoiding the danger of a puncture. The circuit breaker is adjustable through a wide range, and is of the "time limit" type. In this type the acting magnet is shunted by an exposed coil of high-resistance wire. If an excessive current exists for a short length of time, the shunted current flowing through this exposed coil heats the wire and thus sends a larger proportion of the current through the magnet windings and the circuit breaker acts. Momentary currents, such as occur upon starting the motor, or when it is loaded heavily for an instant, are not supposed to open the circuit breaker. Unfortunately, the feeder soon discovers that the circuit breaker can be adjusted to such a point that it will bother him by operating only at long intervals, and at this point he leaves it. Practically, then, the motor must be

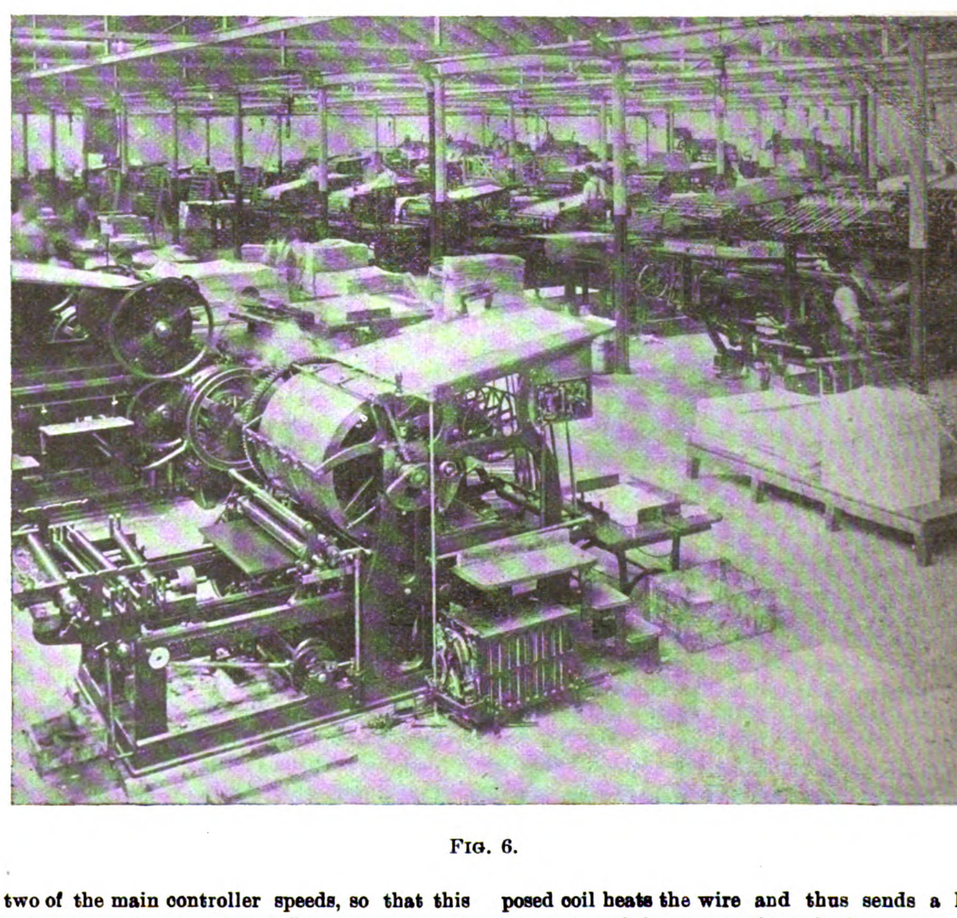

FIG. 6.

protected by fuses, which cannot be adjusted. These fuses are of the inclosed cartridge type and are placed in both sides of the circuit, one being located on either side of the main-line switch upon the panel board. The appearance of the controller and panel board can be seen on the press in the foreground of Fig. 6.

By means of a lever and arm which passes through the bottom part of the press the controller can be operated from the opposite side and the press can be run slowly in either direction in "making ready," without tugging at a belt or without the assistance of the feeder. Push-buttons are located at convenient places about the press frames, with circuits connected so as to shunt the "automatic" magnet attachment, and thus the press can be quickly stopped from any one of a number of points in case of accident.

It is needless to point out that such a model printing establishment as has been described would have been impossible with the old method of transmitting power by means of belts and shafting. The successful operation of this plant is such an emphatic argument in favor of the electrical method of operation that it may be well worth while to review briefly the advantages which have been secured.

The light throughout the plant is entirely unobstructed by belts, so that during the day full benefit is secured of the ideal skylight method of lighting, while at night the operators are not annoyed by shadows, and the amount of artificial illumination required is a minimum.

The predominating idea in the arrangement of the entire plant has been to secure convenience in operation, and the designers of the plant have not been hampered with the necessity of concentrating the machinery near the source of power or of arranging it, in all cases, convenient to long lines of shafting.

The elimination of overhead power-transmitting devices not only takes away the danger of moving belts and revolving pulleys but improves the appearance of the plant, and this is certainly appreciated by the employes, who take pride in the neat appearance of their work rooms.

Without overhead belts and pulleys keeping the dust-laden atmosphere in constant agitation, there is much less waste of stock spoiled by dripping oil or falling dirt—an advantage which it takes a printer to appreciate thoroughly.

The arrangement of the plant over a large area instead of in floors one above another, with belts passing from floor to floor, secures lower insurance rates. The wires running from the engine room to the departments, when once installed, require no further attention. One department may be operated overtime while the remainder of the plant is at rest. The lighter the load the more efficient become the transmitting circuits, while the opposite is true with belts and pulleys. The number of units in operation in the engine room can be varied to suit the changing demand for power, and thus secure an economy which is impossible with one large engine belted to a main driving shaft.

The absolute control of the presses, with their easy and convenient manipulation, when "making ready," and their wide range of speed, allowing them to be run at their fullest capacity, has a great influence in increasing the output of the plant. When a machine is not in operation it is immediately shut down, and there are therefore no "stand by" losses outside of the engine room.

The most important advantage, however, is the saving in fuel. The result of the operation of the new plant is that only about one-third of the amount of coal is burned that was required before the move was made. A part of this saving must be attributed to the design of the power plant, with its modern equipment, so that just how much economy has been gained by the operation of the purely electrical part of the plant cannot be definitely determined.

The Corliss engine was furnished by the Atlas Engine Company; the motors by the Sprague Electric Company; the motor controllers and starting boxes by the Cutler-Hammer Manufacturing Company, and the switchboard and wiring by the Western Electric Company. George C. Nimmons was the architect of the building, Bion J. Arnold consulting electrical and mechanical engineer, and Thomas Sheehan mechanical superintendent. Much of the success of the enterprise is due to the energetic management of the president of the company, W. B. Conkey.

RESEARCHES ON HIGH TEMPERATURES AND THEIR PRACTICAL EMPLOYMENT.*

An important paper has recently been published by Goldschmidt in the *Zeitschrift für Elecktrochemie*, in which he reviews previous works on the use of aluminum in producing high temperatures, and then describes the method he adopts. As is well known, an extremely violent reaction takes place when aluminum unites with oxygen, the estimated temperature of the reaction being about 3,000° C. In order practically to make use of the high temperatures thus obtained, the chief difficulty is so to moderate and control the reaction that it will perform the required work.

The first point to be noted is that it is not necessary to heat up the whole of the reacting mass to the temperature of ignition. It is sufficient to start the combustion at a single point only, but this in itself presents some difficulties. In the preparation of metallic chromium from a mixture of its oxide with powdered aluminum, these difficulties may easily be overcome by applying at any convenient point a small quantity of a mixture of aluminum with a more easily reducible oxide, or preferably a peroxide. Lead oxide, copper oxide, potassium permanganate, and many other substances may be employed for this purpose.

One great advantage of this process is that it admits of the preparation of pure metals free from aluminum; the only precaution which requires to be observed is that the oxide to be reduced must be present in slight excess.

The process is capable of two main applications. In the first place the heat given off by the combustion of a mixture of aluminum with any convenient oxide may be utilized for heating purposes only (welding, etc.), or, secondly, the reducing power of aluminum at a high temperature may be used for the preparation of pure metals or alloys. In either case only slight alterations in the mode of working are necessary. If a moderate heat be required, the reacting mass is diluted by the addition of some inert substance, which, at the same time, prevents the whole mass from melting. A convenient mixture of this sort is composed of aluminum and the cheapest available oxide (*e.g.*, iron ore, sand, etc.), which is then diluted either with a large excess of the same oxide, or with magnesia, lime, etc. If, on the other hand, the metal itself be required, a large excess of the oxide must be avoided, so that the heat which is generated will not only melt the metal, but also the slag (corundum), which then protects the regulus from the action of the air.

The following experiments illustrate the applications of the process: A rivet weighing 3 kilos., such as is used in the construction of bridges, is surrounded by a mixture of oxide of iron, sand, etc., and powdered aluminum, and almost wholly embedded in sand contained in a wooden box. On the top of the small exposed portion of the aluminum mixture is laid a small ball prepared by mixing aluminum powder with a more easily reducible oxide, and into which is inserted a short length of magnesium ribbon. The reaction is started by setting fire to the magnesium ribbon, and as soon as this is done, more sand is placed on the top in order to keep in the heat. If the contents of the wooden box are emptied out after a short time, it will be found that the rivet is white hot and ready for forging.

In a similar way 1 inch iron pipes may be hard soldered at an estimated cost of about 2d.; or, two pieces of wrought iron may be fused (welded) together. The joint so obtained is satisfactory, as can be shown by sawing the pieces through at the joint. It is claimed that such a joint is better than that produced by electric welding, owing to the greater uniformity of heat. By diminishing the quantity of inert material, the iron in the above experiment may be easily melted. Holes may be made through one-half inch wrought-iron plates by igniting some of the reacting mixture on them, and adding more, if necessary, as soon as the reaction has started.

In order to reduce chromium from its oxide, a mixture of this and powdered aluminum is made and introduced into a crucible lined with magnesia. The reaction is started as before, and the mixture then added continuously until the crucible is full. After cooling, the crucible is broken open and the regulus of metallic chromium removed. At the meeting of the German Electro-chemical Society, at which the author communicated his paper, he showed a mass of chromium, weighing 25 kilos., prepared in this way. By making two apertures in the crucible, one for the introduction of the mixture and the other for the outflow of the chromium, the process may be worked continuously, as in the case of the electric furnace.

It is claimed that the temperature attained is higher than in the ordinary electric furnace, and that a given quantity of material can be put through in a shorter time. Moreover, the chromium is also free from carbon or carbides. The slag (alumina) produced in the furnace may be reconverted into aluminum and used over and over again, or it may be used for polishing, since it possesses certain advantages over emery.

Almost all metals may be reduced from their oxides in this way, and the yield is nearly theoretical. The different alloys, *e.g.*, "chrom-manganin," copper-chromium, etc., can also be prepared. The slag from the furnace contains minute rubies, which owe their color to chromium.

For the preparation of pure metals, it is necessary to use pure aluminum; but for heating purposes only, crude (50 per cent.) aluminum may be employed. Besides oxides the oxy-salts of certain metals may be reduced in the same way.

The author looks upon aluminum as a "*heat accumulator*," since it is possible to transport it, and by its union with oxygen develop, wherever necessary, an amount of energy corresponding to that which was originally required for its preparation.

The above is an abstract of an article which may be consulted in the *Zeitschrift für Elektrochemie*, iv., (21), 494.

Lamp Holders for Meterless Consumers.

In some districts in England small consumers whose quarterly bills for electrical energy could not support the burden of a meter rental are charged a fixed price per lamp per annum. The charge can take account of the possibility of exceedingly long burning-hours, but not of the honesty-factor of the consumers, the temptation to put in lamps of higher candle-power than those contracted for being very great. At Kingston, we believe, this difficulty was overcome by using locked holders, but a French firm of manufacturers has found a neater solution. The lamp-caps and holders are made on the bayonet principle, but with three pins and slots instead of two. These are placed in different relative positions for lamps of various candle-powers, so that only the lamp of the right size will fit the holder supplied for it.

ERRATUM.—In our issue of November 2, in the middle of the first editorial column, $1 per thousand should have read $1.50 per thousand.

AN ELECTRICAL SURVEY IN THE BOROUGH OF MANHATTAN, NEW YORK CITY.*

Showing Results of Stray Current Measurements Between Electric Railways, Underground Pipes, Etc, Also Results of Tests on the Brooklyn Bridge.

BY A. A. KNUDSON.

(Concluded from page 262.)

Coming now to the tests, it will be noticed that there is no possibility of reaching the anchor plates other than by connection through the cables themselves, and they being firmly attached to the structure cables make all practically one conductor, and a connection on the structure would mean connection with the cables and consequently with the anchor-plates.

This point therefore being settled, the next thing was to obtain a suitable ground, and on the suggestion of Mr. C. B. Martin, the electrician of the bridge, one of the railway cables was used during that portion of the day when it was not in operation for hauling a bridge train. This was a convenient as well as a good ground; the cable surface being polished bright through friction in passing over the pulleys, it was possible to obtain a good contact, and as it passed over the large drums in the engine room, which were on foundations connecting with engines, water-pipes, etc., it was probably the best ground independent of the structure obtainable. The connection to the structure was made by the use of a two-inch screw-clamp, the wire to the voltmeter being attached to it by the simple means of a screw and washer. Two of these clamps were generally used in nearly all of the previous tests, as they were found very convenient for attaching and detaching quickly to and from hydrants, pillars, etc. The first test under these conditions was made just over the Brooklyn anchorage, where the structure was found to be positive to the ground, with a difference of potential of 2¾ volts maximum, estimated average 1¾ volts.

At the Brooklyn tower another ground connection was made to a water-pipe which ran down the side of the tower and is intended for use in case of fire on the bridge. At this point the reading was 3¾ volts maximum, average 2¾; bridge structure was as before positive. At center of span, structure positive at first, with 2¼ volts maximum, but during the readings there were two reversals, one of them only remaining long enough to obtain a reading, which was 1¼ volts maximum, structure negative. At the New York tower: structure positive to cable ground, with trolley variations ranging from three-fourths to 8 volts, average 2 volts. At New York anchorage: maximum 2¾ volts, average 2 volts, structure positive to ground.

Other tests were made to determine the polarity of the rails of the bridge trains, and they were found positive to the structure, the same as the rails of the trolley road heretofore tested. Let us now consider the question of electrolytical conditions of the cable anchorages, as this point appears to be of high importance in this matter, if not the key to the whole situation in determining whether or not electrolytic action is going on. First—These anchorages are composed of solid stone masonry and are put together with the highest quality of cement; there is no brickwork or mortar in their construction.

Second—The 23 tons of iron composing the plates are set about 80 feet below the top of the anchorage. The distance from the bottom of the plates to mean high water is 3 feet 8 inches at the New York end, 5 feet at the Brooklyn end; there is no earthy matter, salts or alkalis, such as is found prevalent in the streets, which go to make up an electrolyte, so I am informed, in any part of this structure.

I was at first apprehensive that on account of the comparatively short distance between mean high water and the plates at both anchorages there might be opportunity for salt water to reach the plates through seepage or capillary attraction and thereby produce such an electrolyte as to cause corrosion, but have been informed that it is not possible for salt water to reach these terminal plates on account of the distance from the river, the anchorages being over 900 feet from the towers which stand at each side of the river. Even allowing 100 feet for the salt water to work back, there is still ample margin as to distance before salt water can reach these plates; besides this, one of the bridge engineers showed me a plan of the construction of the foundation under each anchorage which consists of heavy timbers 10″ x 10″ and some 12″ x 12″ arranged in 4 to 7 layers, placed a short distance apart, and the intervening spaces filled in with concrete cement.

In view of the tests therefore that have been made showing the structure and cables to be positive at both ends, it is quite possible that a portion of the current straying from the trolley lines, and possibly from the bridge service, finds its way out of the anchor plates through the dampness of the stonework of these anchorages. The construction of these anchorages however is such, as I have endeavored to set forth, that it seems reasonable from the general construction of these piers that the mass of stone and concrete surrounding these plates will not constitute an electrolyte such as would favor electrolysis and thereby cause corrosive action on them.

One of the bridge officials informed me that a certain authority had reported that electrolysis would not attack cast-iron, consequently their cast-iron anchor-plates were exempt from such danger. In the light of recent experience in other cities, that theory is now untenable; for instance I will quote a few extracts from a pamphlet, giving the reports of four experts, besides that of the secretary of the Water Board of the city of Dayton, O., embodying an estimate of cost for repairing the damage.

Mr. E. E. Brownell, C. E., states: "To my surprise I have found in this city a six-inch water main that was corroded to the depth of one-quarter of an inch where the voltage did not average over 1.5 to 2 volts positive to the rails, therefore it is impossible to establish a certain voltage that will cover all cases for low readings."

The following extracts are quoted from the report of Mr. J. H. Shaffer, metallurgist.

He says: "In accordance with instructions from the Board, I have made a careful inspection of the cast-iron water mains at fifteen different locations in the city," and then gives the results of excavations, etc., two of which I will quote:

"1st. This excavation was made at the corner of Washington and Mound streets. It exposed a six-inch main and a ten-inch tee; the pipe was laid in 1874, and the tee in 1888, both were subjected to electrolytic action for about ten years. Both pipe and tee showed great evidence of electrolytic corrosion, the pipe being damaged to an alarming degree, with holes pitted from one-eighth to five-sixteenths of an inch in depth, and covering a large portion of the same. . . The lead caulking was found to be in bad condition, and showed perceptible evidence of leaking. The pipes at this point were nine volts positive to the rails.

"2d. This excavation was made on Germantown street, near Krug. It uncovered a six-inch pipe. This pipe was electrolytically corroded in about the same proportion, with other conditions identical. A lead service pipe was also exposed at this point, and was found to be entirely destroyed."

A quotation from the report of the secretary on an approximate estimate of the cost of replacing water-pipes damaged by electrolysis caused by electric railway currents may also be interesting.

He says: "In calculating the cost of replacing the pipes in the whole affected territory, it is estimated at $77,208.80.

"There is 17,513 feet of pipe that shows a voltage of from two to nine volts positive, and from pieces of pipe removed where electrically charged to this extent, it is found that they have deteriorated 50 per cent. in four years.

"Where they were required, when laid, to withstand a hydrostatic pressure of over 300 pounds per square inch, when tested by J. H. Shaffer, iron expert, after being subjected to 4.5 volts for four years, leaked at 150 pounds pressure."

He also states the following: "At 4.5 volts it has been shown that a six inch pipe can certainly become useless in 5 years."

I have quoted thus freely from this pamphlet for two reasons, one to show that it is a mistake to suppose that cast-iron is not subject to corrosion by electrolysis produced by railway currents, and also to show the penalty to which a city is subjected through permitting such conditions to exist so long that they cause such heavy damages to its property. In the light, therefore, of what has been shown to be the state of affairs in the upper part of this city due to escaping railway currents, as well as the experience at Dayton, O., it appears to be the duty of engineers to exercise every possible precaution against the effects of this invisible element of destruction, which if left to itself will certainly shorten the life of valuable city property.

In the cases found to exist up town it is true that the rails of the road referred to are apparently the principal metals damaged, for the reason that they happen to be positive to the water pipes, but as the escaping current goes into the pipes at one place it must come out at others, and at these places damage may be looked for.

The damages already done and threatened to public works in England by electrolysis has led to the establishment of regulations to prevent such action in the future, and similar legislation may be expected in this country should these conditions be allowed to continue. One of the provisions in the regulations prescribed by the British Board of Trade may be of interest just here. It is to the effect that if the pipe is negative to the rails the potential difference shall not exceed 4.5 volts, and if the pipe is positive to the rails the potential difference shall not exceed 1.5 volts. This appears to be very liberal for the railways, in view of the experience in cities on this side of the water; it is probable however they will be made more stringent as future experience in this direction dictates.

I have purposely avoided elaborating any particular scheme for preventing damage by stray railway currents in this paper, for the reason that methods are perfectly well known to railway companies for confining currents to their proper conductors, such as efficient bonding, and providing a return that will leave no inducement for the current to seek underground pipes in preference to a legitimate conductor. It is simply a question of additional expense. Referring to the incandescent light current which was found prevailing everywhere in this part of the city from the Harlem river to the Battery, passing between all kinds of underground metals, and some on the surface, I do not consider these currents as particularly dangerous at the moment on account of their low voltage, but as before stated, it having been established that a fraction of a volt difference of potential will cause electrolytic action, it then comes down simply to a question of time, when those straying incandescent currents will have to be seriously considered.

In conclusion, I wish to say that these remarks regarding possible damage to public structures through the action of electrolysis have been made with no desire on my part to appear as an alarmist, but to present simple facts as found in these investigations. I believe that too little attention has here-

* A paper read at the 128th Meeting of the American Institute of Electrical Engineers, New York, October 26th, 1898.

tofore been paid to this matter by any of us; perhaps for the reason that electrolytic action being invisible as well as noiseless, it has thus escaped attention, and its baneful effects not fully appreciated. It is my opinion, however, that ordinary caution would suggest that periodical tests should be made in every city by competent parties where a trolley road using a ground return is in operation, and the reports placed before those having authority to deal with the matter. In this way threatened damage by electrolysis to water and other pipes, as well as bridges, might be arrested and finally controlled.

Mountain Railways.

An electric railway is in successful operation in California which is novel in many features.

The initiation and successful construction of such a railway connecting the sea shore with the summits, the pine with the rose, the orange with the snowball, are due to Prof. T. S. C. Lowe, of Pasadena. With the exception of the electric road now in process of construction up the Jungfrau, there is probably no enterprise identical in scope and attractiveness, nor one where greater obstacles have been surmounted.

All the other systems of such mountain roads built for the purpose of making the natural attractions of a region available for the sightseer are constructed on the plan of a revolving cog wheel catching in a center rack-rail and operated by a steam locomotive. One of the roads lands one on top of a sulphurous caldron in the crest of Vesuvius; the Rigi, pioneer of its class in Europe, gives one a delightful glimpse of the mountain meadows of the land of William Tell and its hundreds of glacial lakes; the Pike's Peak rack-rail road lifts one up to an unparalleled view of a vast ocean of gray plains. But on the summits reached by the Mount Lowe Railway every one of the attractive landscape features of the others has been included. Below, seemingly within speaking distance, lies all the beauty of contour, the fragrance, as well as the productiveness, with which we are accustomed to associate the classic lands of the eastern half of the Mediterranean.

The cable incline, which constitutes the first division of this mountain road proper, is one of the most successful railroad devices of its kind in practical use in the world.

The electric power is transmitted by large copper conductors to the Echo Mountain power house, in which is a 100 horse-power electric motor which makes 800 revolutions per minute. By a series of gears the revolutions are reduced from 800 to 17 per minute, which is the speed at which the massive grip-sheave turns. The grip-sheave consists of a heavy wheel which carries some 70 automatic steel jaws. As the wheel revolves, these jaws close and grip an endless cable, to which the cars are permanently attached. By this method there is practically no wear whatever to the cable. It is not strained and chafed by the constant operation of gripping, as on the street railway cars, where the inertia of trains of cars of many tons weight has to be overcome by the gripping of the ever-moving cable.

So much for the incline division. From the end of this, i. e., starting from the Echo Mountain House, begins the overhead trolley road, which reaches the "Alpine Tavern" after a rapid and remarkable ascent by which the very heart of the range is penetrated, and over five miles of steep mountain grades are surmounted in the space of thirty-five minutes. The terminus of this alpine division connects with some thirty miles of most excellent bridle paths and carriage roads, leading in all directions over the crest and through the range.

A cable dispatch states that the newspapers of St. Petersburg, Russia, announce the expected visit to that city of Thomas A. Edison, the inventor, and say that the scientific societies are preparing to give him a brilliant reception.

LONDON NOTES.

[From our London Correspondent.]

In Memory of the Late Dr. Hopkinson.

In memory of her late husband, Mrs. Hopkinson, her son and daughter have presented the sum of £5,000 for the purpose of extending the engineering laboratories at Cambridge University. This was a work which the late Dr. Hopkinson took a special interest in, and only a few days before his death he was talking to Prof. Ewing of opening a subscription fund for the purpose.

Electric Traction for London.

The London County Council is giving earnest consideration to the question of electric traction. At the beginning of 1899 there will come under its control 70 or 80 miles of horse trams in London, therefore the fact that it is looking into the question of electric traction is important. The Council proposes allowing a tramway company to put up the trolley for about a couple of miles in one of the suburbs, and one of its own members, Mr. Baker, has issued by request a very elaborate report on electric tramway work generally. He compares the costs of various methods and ends by recommending the introduction of the underground conduit, in spite of the fact that its initial cost is considerably more than that of the trolley, because he says it is the one best suited to the requirements of London's busy thoroughfares. Mr. Baker also considers gas, oil, steam, cable and other forms of traction. He tells the Council that for horse traction they will have, when they take over the lines, to pay from 50 per cent. to 100 per cent. more than by the electric system for maintenance and working. It is probable that there may be some decided move shortly in this matter. The Council is to have a debate on the entire subject in a day or two.

CANADIAN NOTES.

The statement of the Montreal Electric Street Railway for the last year shows the net profits to have been $601,704.18, against $507,885.60 for the year previous. After paying a 10 per cent. dividend $138,000 was carried over to the rest account.

The new fender which will be used on the cars of the Ottawa Electric Street Railway was successfully tested this week. The new fender is an ingenious invention of the Consolidated Fender Company of Providence, R. I., and all the cars will shortly be equipped with them at a cost of over $5,000, or about $80 per car. The fender is about six inches from the rail and is so constructed that by the motorman touching a spring the appliance immediately drops and picks up the object in front of it.

For the past two weeks there has been an experiment going on in Ottawa which has now developed into an industry. It is the manufacture of calcium carbide for the production of acetylene gas by means of a new yet simple and effective method. The inventors of this new scheme are Messrs. H. Lamoth and J. W. McRae of Ottawa. The new idea is in the furnaces which are to be used in the manufacture of the carbide. The ingredients used are coke and limestone, the two being mixed in proper proportion and thoroughly purified. The furnace to be used is a simple construction and is heated by electricity. The furnace consists of two electrodes, one suspended from above and the other placed on the ground. The two are connected by means of carbon pencils which form an arc producing sufficient heat to melt the coke and limestone which is piled around these electrodes, and form it into calcium carbide. It is the intention of the promoters of this new industry to erect a plant containing about 40 of these furnaces which will be kept running 16 hours per day. The carbide is produced for $60 per ton wholesale and the factories now making this product throughout Canada are unable to keep up with the orders now flowing into them. By operating their present plant the inventors expect shortly to be able to turn out about 10 tons of carbide per day.

LEGAL NOTES.

John M. Sellers and E. A. Noonan have filed a petition in St. Louis for a receiver and an accounting for the St. Louis Underground Service Company and the Citizens' Electric Light & Power Company. The petitioners charge the officers with conspiracy to defraud the stockholders. A reorganization of both companies is requested.

In the third trial of the Jessie Krueger damage suit against the West Chicago Street Railway Company, at Chicago on the 28th ult., Judge Hutchinson discharged the jury, who were unable to come to an agreement, and a fourth trial will probably result. Miss Krueger asked for $75,000 damages. She was run over by a car of the West Chicago Street Railway line on June 27, 1892, and received injuries which necessitated the amputation of her left leg. The case was first brought to trial in 1896 and the jury awarded the plaintiff $50,000. The Appellate Court ordered a new trial, which was begun last February. It was abandoned because of the death of a juror. The third trial resulted as above stated.

A Customs Decision.

The Board of Classification of the United States General Appraisers have announced a decision regarding the tariff on incandescent electric lamps. The Collector at New York assessed a duty of 60 per cent. ad valorem, under paragraph 100, Act of 1897, which covers various articles of glass, or of which glass is the material of chief value, and blown glassware. A protest was filed by the importers, Knauth, Nachod & Kuhne. The board holds that while glass is the component material of chief value, yet the other materials, carbon filament, porcelain, metal and cement, are so essential to the character of the lamp that it ceases to be merely blown glassware. The board holds further that the goods are covered by paragraph 112, which includes manufactures of which glass is the component material of chief value, not specially provided for. The protest is sustained and the duty fixed at 45 per cent.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING.

Baldwin, Wis.—Peabody & Sabby have formed a copartnership to put in an electric lighting system here.

Birmingham, Ala.—Three electric light plants will be erected at Pratt City and Ensley. One of the plants is to supply light and power for Pratt City; the others are smaller plants, one at the Ensley City steel plant and one at the Semet-Solvay by-product works.

Camden, N. J.—An ordinance has been introduced in the city council giving the Citizens' Heat, Light & Power Company the right to string wires and erect poles in the streets.

Columbus, Wis.—Local business men and capitalists are contemplating putting in an electric light plant upon such terms that the city will at the expiration of twenty years become the owner of the plant.

Dolgeville, N. Y.—The Dolgeville Electric Light & Power Company of Dolgeville has filed a certificate with the Secretary of State announcing that its number of directors has been decreased from thirteen to five.

Grand Rapids, Mich.—Manager Chase of the Chase Construction Company is in the city making preparations for beginning work on the contract for installing the municipal electric lighting plant. He expects to employ about 100 men.

Green Bay, Wis.—It is stated that negotiations for the sale of the plant of the Green Bay Gas & Electric Light Company have been closed. The A. M. Sutherland Company of New York, Sinclair Mainland of this city, and William Mainland of Oshkosh are the principal investors. The purchase price is withheld. Bonds to the amount of $125,000 have been subscribed for and $50,000 will be spent in improvements.

Hagerstown, Md.—The town council has taken the initial movement looking to the establishment in Hagerstown of an electric lighting plant. The town is empowered to borrow $60,000 for an electric plant. The mayor will appoint a committee of citizens to report on the subject.

Johnstown, Pa.—The city authorities have closed a five-year contract for street lighting with the Johnstown Electric Company, calling for 204 arc lights of 2,000 candle power each. Under the new contract the city saves $2.50 on each light from the price formerly paid.

Lancaster, Pa.—The select and common councils have passed an ordinance approving of the assignment of the city lighting contract held by Gustavus Groezinger and associates to the Lancaster Electric Light, Heat and Power Company. The company has filed its acceptance of the ordinance. It has also executed a mortgage for $100,000, the proceeds to be applied to increasing the capacity of the plant.

Malone, N. Y.—The trustees have granted a franchise to Messrs. Kilburn, Wright and Abbott authorizing them to set poles and string wires in the village for the purpose of conducting an electric lighting and power business.

Odessa, Mo.—A stock company is to be organized here to put in a $5,000 electric light plant.

Perrysville, O.—E. H. Vanderslice proposes to use the water power that formerly ran the Perrysville flouring mill to operate an electric plant for lighting purposes. He has secured contracts for over 100 incandescent lights and expects to get 300.

The Dalles, Ore.—Mayor Nolan has vetoed the ordinance providing for lighting the city streets by means of electricity. Among the reasons given by the mayor is the important one that the finances of the city do not justify the council in making the contract.

Winona, Miss.—A company has been organized here to put in an electric lighting plant if the city votes to take street lights. The company is composed of local business men and will establish a first-class plant.

STREET RAILWAYS.

Albany, N. Y.—The board of trustees of the village of Ravenna have lately visited this city for the purpose of interesting capitalists in the proposed electric railway from Albany to Ravenna. The project to build a road through the villages of Ravenna, Coeymans, Indian Fields, South Westerlo, Preston Hollow, Clarksville and Rensselaerville has been under advisement for some time, but it has been decided to make the attempt on a larger scale than before contemplated. It is proposed to make it a freight carrying concern.

Atlanta, Ga.—The Atlanta Railway Company has been granted the franchises for streets on the west side which it asked for and will prove a formidable competitor of the Consolidated Street Railway Company. The latter company had practically a monopoly of the street car business in Atlanta.

Boston, Mass.—The Boston & Maine Railroad Company has decided to equip its Portsmouth & Dover branch, about ten miles in length, for electrical operation, the power to be furnished from a power house on Noble's Island, which will also supply power for the Portsmouth, Newcastle & Rye Electric Street Railway.

Dayton, O.—The surveys for the Dayton, Spring Valley & Wilmington interurban electric road are being made, and in a few days work on the construction of the power house will begin.

Camden, N. J.—An ordinance has been introduced in the city council giving a number of Philadelphia capitalists the right to erect and operate an elevated electric railway in Camden as part of a system connecting with Atlantic City.

Chicago.—The Calumet Electric Street Railway Company has installed two passenger elevators at its new terminal station at the corner of 63d street and Stony Island avenue. The elevators are capable of hoisting passengers to the station platform, 32 feet above, at the rate of 100 a minute.

Cumberland, Md.—The county commissioners will be asked at their next meeting for their consent to the projected route for an electric railway between Cumberland and Westernport. As soon as this is granted the survey will be made.

East Liverpool, O.—A syndicate of New York, Chicago and Philadelphia capitalists will build an electric freight line between this city and Lisbon, connecting the Erie system with the Ohio river. The road will pass through the richest undeveloped coal field in Ohio, and the syndicate has secured options on 18,000 acres of coal land. The new road and the mining plant will represent an investment of $700,000.

Exeter, N. H.—Superintendent E. E. McReel of the Exeter-Hampton Street Railway states that work on the extension of the road to the New Hampshire State line will be pushed in order to have the cars running if possible by December 10 over that section. About five and a half miles of track is to be laid.

Geneseo, N. Y.—There is talk of a stock company being formed to build an electric road from Mt. Morris and Geneseo to Conesus lake.

Hartford, Conn.—The "Times" says it is reported that an agreement has been reached between Jesse W. Starr and George H. Dunham, the rival street railway promoters and petitioners for franchises in West Springfield and Agawam, under which the Dunham petitions were withdrawn and both men will do their utmost to secure the franchises petitioned for by the Starr company.

Jersey City, N. J.—Mayor Hoos has signed the ordinance granting the North Hudson Railway Company permission to operate the cars on the Grove street line, connecting Jersey City with Hoboken, with electricity instead of horse power. The franchise is perpetual, and the company agrees to pay the city $600 a year.

Lansdale, Pa.—The Inland Traction Company, whose object is to build a trolley line from Perkasie to Lansdale, has received a charter.

Lincoln, Ill.—The Lincoln Electric Light & Street Railway Company has been granted a forty years' extension of its franchise.

London, Eng.—Albert Johnson, brother of Tom Johnson, the Ohio trolley magnate, has arrived here and is holding consultations with electricians and capitalists concerning the project of introducing electric roads in London and other English cities. London has now an underground electric road, but there is a demand for surface roads extending to outlying districts. Mr. Johnson says there is no city in the world that offers such advantages for the establishment of the American trolley system. A company is already formed to promote electric roads in the city, with a capital of £1,000,000 sterling, and if the necessary street privileges are obtained from the city council, electric surface lines will speedily be built in several sections of the city.

Marysville, O.—M. A. Wright, of Maple Dell, representing a company of wealthy capitalists, has applied to the county commissioners for right of way for an electric railway connecting Richwood, Pharisburg and Magnetic Springs with Marysville.

Merrill, Wis.—The Merrill Electric Railway & Light Company has decided to rebuild its electric plant and will begin the work at once.

Milford, Mass.—A party of Worcester, Westboro and Milford capitalists have associated together for the purpose of building an electric railway from Milford to Westboro via Hayden Rowe and Hopkinton, and have formed a corporation known as the Westboro, Hopkinton & Milford Street Railway Company. The capital stock of the company is $80,000, and the length of the road is 8 miles. William S. Reed of Leominster, Joseph G. Ray of Franklin, Edgar K. Ray of Franklin, M. H. Walker of Westboro, Charles B. Tewksbury of Westboro, Frank W. Wood of Hopkinton and Horace Wood of Hopkinton are the temporary directors.

Montpelier, Vt.—A bill has been introduced in the House to incorporate the Swanton Electric Railroad Company which proposes to build and operate roads in the towns of Franklin and Highgate. The capital stock is placed at $100,000 with power to increase. The incorporators named are H. M. Stone, C. C. Gilmore, H. A. Burt, F. J. Hawley, W. C. Butterfield, C. H. Reynolds, L. H. Felton and C. G. Austin.

Mt. Vernon, N. Y.—The council has awarded a franchise to the Westchester Electric Railway Company, some of the conditions of which are that the company shall carry passengers from Mt. Vernon to the Harlem River for 5 cents, run cars under a five minute headway, and pay 3 per cent. of its gross receipts into the town's treasury. The franchise is to run fifty years and requires that the company give a bond for $25,000 for the carrying out of the agreement.

New York.—In the November number of the "Street Railway Journal," President H. H. Vreeland of the Metropolitan Street Railway Company has an article in which he compares the operating costs of the various systems. He says: "For the year the operating expenses of the cable lines were 16.42 cents per car mile, of the horse lines 17.87 cents, and of the electric lines 10.23 cents. For the three months period, which is more favorable to electric operation, the cable lines cost 17.55 cents, the horse 17.89 cents, and the electric 10.06 cents. During the twelve months period the cable lines operated at 47.7 per cent. of their passenger receipts, the electric lines at 37.9 per cent., the horse lines at 65.3 per cent., and the entire system at 53.3 per cent. During the three months period the cable lines operated at 52.7 per cent. of their passenger receipts, the electric lines at 38.6 per cent., the horse lines at 62.1 per cent., and the entire system at 50.9 per cent."—The Third Avenue Railway Company has a large number of men at work excavating along its Third avenue line for the change in motive power from cable to underground trolley. It is expected that the new system will be ready within four months.

Norwalk, O.—It is authoritatively stated that a new electric road will soon be built between this city and Sandusky. Clark Rude of Sandusky and W. W. Graham of Norwalk are taking an active interest in the scheme and are said to have secured plenty of Eastern capital for the enterprise.

Oswego, N. Y.—Receiver Frederick H. Tidman of the Lake Ontario & Riverside Railway Company has announced that the street car service of the company will be discontinued until further notice. The road has been running behind at the rate of $100 a week. Some betterments are to be made on the road, which are expected to greatly increase the patronage.

Owosso, Mich.—The projectors of the electric railway between Pontiac and Owosso agree to have cars running by the 1st of January. The line will be an extension of the Detroit & Pontiac road.

Portland, Ind.—The Albany, Dunkirk & Camden Traction Company and the Camden, Dunkirk & Albany Traction Company, rival lines for the purpose of constructing a road between Camden and Albany, passing through the city of Dunkirk, have consolidated their interests, and the general expectation now is that the work will be hurriedly pushed.

Redlands, Cal.—Henry Fisher, J. H. Fisher and O. H. Childs have purchased a controlling interest in the Redlands Street Railway with intent to change the motive power of the road to electricity. Bonds to the amount of $50,000, bearing interest at 6 per cent., will be issued for the purpose.

St. Louis.—The Lindell Railroad bill passed by the city council has been approved by the mayor.

Washington, D. C.—The amount of street railway trackage operated by the various companies in this city is as follows: Capital Traction, 16 miles; Metropolitan, 12 miles; City and Suburban, 25 miles; Columbia, 2.86 miles; Brightwood, 5 miles; Washington and Great Falls, 3½ miles. This includes single and double track.

MANUFACTURING, ETC.

New Haven, Conn.—It is reported that as a result of the recent purchase of the Walker interests by the Westinghouse Company, the local branch of the Walker Electric Company will be removed at once to Pittsburg.

New York.—The report in press dispatches from Chicago that the Siemens & Halske Company of America were considering a proposition from the Japanese Government to form a Chicago syndicate with a capitalization of $10,000,000 to establish electric street car lines and electric plants for lighting and power throughout the empire, is doubted by the Japanese Consul in this city, who is reported in the "Commercial" as saying: "I doubt if there is the slightest truth in the report. The Japanese Government has not the power to grant such a franchise. It may be possible that there is an effort being made to secure American electrical appliances by private individuals in Japan; but as for granting exclusive privileges to American electric companies, I do not credit it." In the dispatch referred to it was stated that Messrs. Elkins and Widener of Philadelphia would be included in the syndicate, but they have since asserted that they had absolutely no knowledge of the matter and that no such step was contemplated by them.

Paris, France.—Commissioner Peck has been officially notified that 5,000 additional feet of space had been allotted to the United States at the Exposition, making a total of 40,000 feet additional to the original concession.

Washington, D. C.—The "Times" states that J. E. Powell, who will have charge of the electrical display of the American exhibit at the Paris Exposition, and who has just returned to Washington from Paris, is enthusiastic over the proposed representation of the United States at the Exposition.

TRANSMISSION PLANTS.

Denver, Col.—The Board of Aldermen has granted a franchise to the Denver Power & Irrigation Company to erect poles, string wires and build conduits for the purpose of transmitting electricity into Denver for light, power and heat from its proposed transmission plant to be erected at the head of Platte canon. Rhodes Bros., Equitable Building, Denver, are the promoters of the enterprise.—Theodore F. Van Wagenen, a mining engineer of this State, is stated in the "Republican" to have completed one of the most extensive plans for electric power for placer mining in the West. The plant is located in the Boise basin of Idaho, and is to supply power for placer mining to two companies organized by the Basic Company of Philadelphia—the Bed Rock Dredging Company at Placerville and the Boise Dredging Company at Centerville. The power plant was constructed under the superintendence of Mr. Van Wagenen.

Santa Fe, N. M.—An electrical generating plant is to be built at Cochite to run by water power, and all the mines in the surrounding country will, it is expected, be supplied with power from the plant.

Seattle, Wash.—The "Post Intelligence" of the 23d ult.: says: "The Sunset Falls Power Company is already preparing to create a use for the electric power to be generated at Sunset and Eagle Falls on the Skykomish river. It has sent a party of engineers to survey a line for an electric railroad from Index up the north fork of the Skykomish to Galena. It is proposed to follow the south bank of the north fork as far as Trout creek, then to cross by means of a bridge and run along the north bank for the rest of the distance."

COMPANY MATTERS.

Albany, N. Y.—A certificate of the voluntary dissolution of the Compressed Air Power Company of New York City, was filed on the 29th ult. with the Secretary of State. This was a Metropolitan Street Railway corporation, which was organized when the question of using compressed air as a motive power on the system of the Metropolitan Traction Company in New York was being discussed, but it dissolved owing to the determination to install the underground electric trolley system on the street surface railway lines of the Metropolitan Company.

Brooklyn, N. Y.—Internal Revenue Collector Moore of this city has received a decision from the Washington authorities to the effect that the Edison Electric Illuminating Company of Brooklyn must pay a revenue

tax of $5,000 on a mortgage of $10,000,000 recently executed by the company to secure a like amount of bonds which the stockholders had agreed to issue. When the mortgage was executed the Edison Company submitted the documents to Collector Moore for an opinion as to the amount of tax the company would have to pay under the War Revenue act. As only $2,000,000 of the bonds are to be issued at present the company believed that it was liable to a tax upon that amount only. Commissioner Scott, however, holds that the instrument is subject to taxation as a mortgage for $10,000,000.

Norfolk, Va.—Judge Waddill of the U. S. Court has appointed B. Watkins Leigh receiver of the Portsmouth & Port Norfolk Electric Railway Company. The action was taken on the application of the Mercantile Trust & Deposit Co. of Baltimore, trustee under a mortgage given by the company, and M. E. Decker, of New Jersey, who furnished supplies. The receivership was a surprise to people here, as the sale of the line to a company of wealthy Northern men was momentarily expected.

NOTES FROM A CORRESPONDENT.

Albany, N. Y.—Open competitive civil service merit examinations for positions in the State service will be held Dec. 3 in the following cities: Albany, Amsterdam, Auburn, Binghamton, Buffalo, Dunkirk, Elmira, Geneva, Hornellsville, Ithaca, Jamestown, Kingston, Little Falls, Lockport, Malone, Middletown, Newburg, New York, Ogdensburg, Olean, Oneonta, Oswego, Plattsburg, Poughkeepsie, Rochester, Rome, Sandy Hill, Schenectady, Syracuse, Utica and Watertown. Among the positions for which examination is held are that of chief electrical engineer and assistant electrical engineer.

Schenectady, N. Y.—Complaint has been made for some time past that wire and other material has been stolen from the General Electric Works. The police has succeeded in arresting a man who was carting away about a ton of copper wire which was identified as belonging to them by the General Electric Company. The thief refused to tell the names of his accomplices.

PERSONAL AND MISCELLANEA.

The Cincinnati "Post" says that letters have been received from Col. H. P. Bradford, now in Mexico City, Mex., formerly general manager of the Main street car line in Cincinnati. Mr. Bradford is now general manager of the Mexican Consolidated Street Railway Company, and is converting the system from a mule service into an electric line.

The Portsmouth, O., "Times," in stating that the contract for electrically equipping the Burgess mill in that place was awarded to the Westinghouse Company, says that "Mr. Hodge, the clever little representative of the Westinghouse people, was greatly elated over his success, and that night took his rivals for the contract—the representatives of the General Electric Company and the Triumph Company—to the Opera House to see 'A Stranger in New York.'" Hodge evidently has good stuff in him.

The new power house of the Hagerstown, Md., Electric Railroad Company has been singularly unfortunate. During its construction, which has been going on for several months, the walls when near completion have been twice thrown down by storms, and a few days ago the last of the iron roof trusses was being placed in position when it swayed and fell, displacing the other girders, all going down in a mass, crushing out the newly erected walls, and leaving the structure a heap of ruins for the third time. Several of the workmen were injured on the last occasion and two of them will probably die.

The New York correspondent of the Philadelphia "Press" refers to Mr. Nikola Tesla's wireless aerial transmission discovery in a dubious spirit. After calling attention to the fact that several of Mr. Tesla's most boldly announced devices have failed to materialize after publication, he goes on to say: "There have been promises made in his name for wireless telegraphy, but Marconi seems to have achieved where Tesla only promised. This last invention of his comes well within the description made by Lord Kelvin when he was here a year ago of the improbable possibilities of electric development. Lord Kelvin said that there were two peculiar tendencies on the part of those who were carried away by the romance and fascination which electricity furnishes, one being to make prediction of probable impossibilities and the other to make prediction of improbable possibilities. Scientists here and capitalists as well look upon Tesla's promise to convey electricity of enormous voltage through the upper air to convenient stations as being of the class described by Lord Kelvin as improbable possibilities."

E. L. Anderson of St. Louis, the electro-chemist of the Phoenix Carbon Company, has, it is stated, made a discovery "that will startle the electrical world." It is claimed that he has discovered a process of manufacturing and conducting electricity without the aid of dynamos, engines, or any of the ordinary apparatus. The "Star" says he has succeeded in interesting several parties of good financial standing in his invention and has applied for a patent. "The process as far as can be learned," the same paper says, "consists of a jar of water, into which is put a chemical that has the power of drawing a certain oxygen out of the air. The solution of the air and water produces the electricity. These jars are placed beneath the seats of cars or vehicles, in the basements of buildings and residences, and are connected by means of wires. It is only necessary to refill the jars once a month with water."

RECENT COMPANY ELECTIONS.

Chattanooga Electric Railway Company, Chattanooga, Tenn.—President and treasurer, J. H. Warner; vice-president and secretary, Edwin Warner; directors: J. H. Warner, Edwin Warner, Capt. Charles A. Lyerly and Frank Spurlock, of Chattanooga; Percy Warner, of Nashville, and G. W. Meade, of Brooklyn, N. Y.

East Wareham, Onset Bay & Point Independence Street Railway Company, Onset Bay, Mass.—President, Joseph K. Nye of Fairhaven; secretary and treasurer, Anderson W. Kelley of Fairhaven; directors: Fred L. Benson of Onset Bay, Capt. Benjamin F. Gibbs of East Wareham, and William F. Nye of Fairhaven.

Exeter Street Railway Company, Exeter, N. H.—President, William Lee; treasurer, Charles E. Hollander; clerk, John Templeton; directors: Charles A. Cotton, W. D. Lovell, Charles E. Hollander, William Lee and R. E. Hastings, all of Boston; Warren Brown of Hampton Falls, and A. E. McReel of Exeter.

Joliet Street Railway Company, Joliet, Ill.—President, Weston F. Milliken; vice-president, George T. Duncan; treasurer, Henry P. Cox; secretary, Henry Woodman, all from Portland, Me.; manager, William B. McKinley, Chicago; superintendent, C. O. Rush, Joliet.

Thomson-Houston Electric Light Company, Quincy, Ill.—President, Frederick Wilms; vice-president, Capt William Steinwedell; secretary and treasurer, Frank A. Parker; superintendent, W. E. Steinwedell; directors: the officers and H. F. J. Ricker, J. M. Haynes, Col. William McKinley and L. E. Emmons.

Wilkes-Barre Electric Light Company, Wilkes-Barre, Pa.—President, Abram Nesbitt; vice-president, J. W. Hollenback; secretary and treasurer, E. W. Mulligan; directors: the officers and John Flanagan, Liddon Flick, W. P. Billings, E. H. Jones, Charles W. Lee, W. A. Lathrop, E. C. Jones and Irving A. Stearns.

Winchester Avenue Street Railroad Company, West Haven, Conn.—President, W. B. Furgeson; vice-president and secretary, I. A. Kelsey; treasurer, John F. Prince; superintendent and general manager, Albert E. Pond.

COMMERCIAL PARAGRAPHS.

The Lombard Water Wheel Governor Company, 61 Hampshire street, Boston, Mass., has recently issued an attractive catalogue descriptive of its well-known water-wheel governors. The work is fully illustrated by half-tones showing various plants in which the Lombard water-wheel governors have been installed. The last few pages of the catalogue are devoted to testimonial letters, all speaking very highly of the excellent regulation in speed obtained by the use of the Lombard governor.

The Consolidated Incandescent Light Company of 510 West 53d street, New York—operating and controlling the Apollo Incandescent Gas Light Co., the Victor Incandescent Co., the Star Incandescent Gas Light Co., and the Ideal Lamp Co.—have on hand at all times a large and select assortment of Apollo and Ideal burners, Apollo and Victor mantles, and glass shades and chimneys of all descriptions. The prices at which these goods are sold are extremely low considering the quality, and any one interested can secure, free of charge, a monthly price sheet by sending name and address to the company.

We are in receipt of catalogue No. 4, just gotten out for 1899 by Messrs. Huebel & Manger, 286-290 Graham street, Brooklyn, manufacturers of electrical and brass goods. This pamphlet of 50 pages is very attractive in appearance and fully illustrated. The above parties have at all times on hand a large and select assortment of electric bells and buzzers, push buttons of every description and design, binding posts, switches, speaking tubes and letter boxes. Judging from the catalogue the prices are moreover reasonable.

One of the greatest problems which present themselves to every electric light station manager is the proper protection of electrical machinery from damage by lightning. Anything leading to a proper solution of the problem is always welcome. The Electric Appliance Company of Chicago have just issued a special circular of Wurts Lightning Arresters which embodies all of the improvements to date in this class of apparatus and gives some valuable hints with reference to protection from lightning.

Three very handsome and fully illustrated catalogues have been sent us by the C. W. Hunt Company of Staten Island and 45 Broadway, New York. The first of these discusses very fully the advantages to be derived by the introduction of industrial railways in manufacturing establishments and illustrates apparatus of this nature manufactured by this well known concern. This little work is so well gotten up and contains so much valuable information that it should be in the hands of all those interested in the conveying question. The second catalogue is entitled "Mast Fittings, Coal Tubs, Hoisting Blocks, Wheelbarrows," and each of these subjects is taken up, discussed, and the high grade of apparatus manufactured for these purposes by the Hunt Company illustrated. The third catalogue, on the subject of "Manila Rope for Transmission and Hoisting," is even more complete than the two catalogues mentioned above, containing as it does formulas, tables and general data of value in mill engineering. This little work, comprising 40 pages of valuable information, should certainly be in the hands of all engineers in any way interested in power transmission for factories or mills.

The accompanying illustration shows the latest type of Edison Jr. incandescent lamp, which would seem to be rapidly growing in favor judging from the large number of orders the company is reported to be receiving. That this lamp has a long life and maintains its initial candle

power is now an established fact. At the recent Peace Jubilee in Philadelphia several thousands of these lamps were made use of for decorative purposes, giving general satisfaction. How well the Edison Jr. lamp is getting to be thought of may be gathered from the following communication:

Tuxedo Club, Tuxedo Park, N. Y., Oct. 3, 1898.
Thomas A. Edison, Jr., 27 William street, New York.

Dear Sir: Please pardon my long delay in acknowledging the receipt of your letter of May 26, and the three 16 CP., 105 volt, Edison base, Edison Jr. improved lamps.

Have had the three sample lamps in continuous service since receipt; have shown them on the banquet tables, in octagonal pyramids of ice. "Oh, how beautiful!" I can say they have won for you our trade.

In a few days I will have the Club order sent for our supply of lamps.

Please write me, do you pack 200 or 250 in bbl. lots.

Yours truly, E. I. WILBUR.

During the past summer the Joseph Dixon Crucible Company of Jersey City, N. J., have added an extension to their pencil factory, 40 by 90 ft., three stories high. The same is driven by electric power from a generator placed in the main factory. No expense has been spared in the equipment of this addition in the way of up-to-date elevators, furnaces, dry-rooms, etc. The company will also put down an artesian well, several hundred feet in depth, for a supply of water for factory use, and some time during 1899 various other additions will be built to the Dixon Company's very extensive plant. The Dixon Company was established in 1827, but during all of its more than threescore years and ten of busy life, no year has yet in any way equaled 1898 for volume of business; its plant has been running continuously, yet the company is behind its orders in all departments. As the Dixon Company's products go into every known field of industry—the iron workers, the brass workers, the printing trades, the stationers, the cycle manufacturers, the hat manufacturers, the paper mills, etc.—the rise or fall of the volume of business done by the Dixon Company may be taken as a very excellent standard or pointer on the condition of business generally.

INVENTORS.—We neither purchase nor sell your patent, but we examine and report on it to you. If it has merit we furnish endorsements of experts that commend it to capitalists—and those who can use it. Correspondence solicited. Fees moderate. Address

EXPERT, care ELECTRICITY.

INCORPORATIONS.

The Waterbury Battery Company, Waterbury, Conn. Capital stock, $10,000. Incorporators: C. Platt, Charles B. Schaumacht and O. M. Platt.

The International Fac-Similigraph Company, Cleveland, O.—to manufacture devices for electrical transmission of photographs. Capital stock, $25,000.

The Joplin Illuminating Company, Joplin, Mo. Capital stock, $80,000. Incorporators: John C. Porter, Harrison J. Dunham, Francis Kuhn and Charles Nelson.

The Camden, Dunkirk & Albany Traction Company, Camden, Ind. Capital stock, $150,000. Incorporators: G. W. and J. A. Simpson of Chicago, and George W. Whittaker of Dunkirk.

The Montezuma & Oglethorpe Light Company, Montezuma, Ga.—to operate electric and other lighting plant. Capital stock, $3 000. Incorporators: Jule Felton, V. O. Brown and S. K. Brown.

The Albany, Dunkirk & Camden Traction Company, Albany, Ind. Capital stock, $25,000. Incorporators: H. Clay Billingsley, John E. Billingsley, W. F. Machlan and G. L. Sullivan.

The Cincinnati, Lawrenceburg & Aurora Electric Street Railway Company, Aurora, Ind. Capital stock, $10,000. Directors: J. C. Hooven, George H Helvey, G. A. Reutchler, C. E. Hooven and Fred H. Shafor.

The Sands Electric Company, Cleveland, O.—to manufacture all kinds of electrical appliances. Capital stock, $10,000. Incorporators: L. Sands, Edward Velhagen, F. B. Skeels, C. R. Hunt and O. A. Bejck.

The Abbott Electric & Manufacturing Company, Cleveland, O.—to manufacture electrical and mechanical devices. Incorporators: H. H. Hammond, H. I. Wickes, William A. Marbach, Samuel Abbott and C. B. Abbott.

The South McAlester Electric Light Company, Fort Smith, Ark. Capital stock, $25,000, of which $5 000 is paid in. Incorporators: L. G. Graham, J. T. Miller, W. J. Wade, Joseph R. Foltz and W. P. Andrus of Fort Smith.

The Edison Junior Electric Light & Power Company, New York. Capital stock, $500,000. Incorporators: Thos. A. Edison, Jr., S. R. Valentine Robinson, H. C. Hepburn, E. A. Drake, C. S. Henry, R. M. Jordan, J. G. Batterson, Jr., and F. J. Stone.

The Citizens' Light, Heat & Power Company, Camden, N. J.—to manufacture electricity for light, heat and power. Capital stock, $100,000. Incorporators: Andrew S. Scull and Joachim R. Moon of Camden, and Wesley Bartine of Philadelphia, Pa.

Three charters were recently recorded in the office of the recorder of deeds at Media, Pa. They were for the Darby-Lansdowne Electric Company, the Clifton-Lansdowne Company and the Yeadon-Lansdowne Company. These companies are formed for the purpose of furnishing heat, light and power to the various boroughs. Those interested are: T. P. Street, H. C. Statzell, M. J. Kelly, J. M. Lutz, R. Shoemaker, E. T. Bishop, N. J. Mitchell and E. R. Lewis.

ELECTRICAL PATENT RECORD.

Letters Patent Issued November 1, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

613,301. Yoke for Railway-Conduits. Fred S. Pearson, Boston, Mass. Filed Nov. 4, 1897.

613,357. Suspension for Electric Railway-Motors. William Cooper, Cincinnati, O., assignor to John B. Blood and Joshua Hale, Newburyport, Mass. Filed Aug. 16, 1898.

613,418. Electric Railroad. Charles L. Kemery, Pittsburg, Pa. Filed Jan. 12, 1898.

613,483. Electric-Railway System. Louis E. Walkins, Springfield, Mass., assignor of one half to George M. Jewett, Glenville, Md. Filed Nov. 18, 1897.

613,825. Car-Fender. John Sexton, Los Angeles, Cal. Filed May 27, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

613,248. Incandescent-Electric-Lamp Holder. George W. Cook, Jr., Bloomfield, N. J. Filed Nov. 5, 1897.

613,293. Mechanism for Supporting Electric-Arc Lamps. William A. McCallum, Avondale, Ohio. Filed Nov. 18, 1895.

613,406. Electric Car-Lighting William Biddle, New York City, assignor to the American Railway Electric Light Company, same place. Filed May 14, 1894.

613,647. Insulator for Incandescent Electric Lamps. Charles W. Brown, Boston, Mass., assignor, by mesne assignments, of one-half to Laroy S. Starrett, Athol, Mass. Filed Dec. 15, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

613,848. Printing-Telegraph. Aloys Wirsching, New York City. Filed May 10, 1897.

613,533. Telephone Box or Cabinet. Ishmael Sparks, Santa Fe, N. Mex. Filed March 22, 1898.

SIGNALS AND SIGNALING APPARATUS.

613,549. Grade-Crossing Signal for Railways. Harry M. Abernethy, Elmira, N. Y., assignor to the Eclipse Switch & Signal Company, Camden, N. J. Filed Sept. 9, 1897.

613,567. Block-Signaling Apparatus. Taylor T. Fogel, Allentown, Pa. Filed Dec. 6, 1897.

MISCELLANEOUS.

613,286. Emergency Fusible Cut-Out for Electric Circuits. Charles H. Long, Louisville, Ky. Filed July 10, 1897.

613,309. Electric Ignition Device for Internal-Combustion Engines. Louis W. Ravenez, Paris, France, assignor to the Societe Nouvelle des Etablissements, Decanville Aine, same place. Filed March 7, 1898.

613,367. Electric Rotary Cutter. Fulton Gardner, Chicago, Ill. Filed March 19, 1897. Renewed Jan. 24, 1898.

613,420. Electric Vehicle. Karsten Knudson, Chicago, Ill., assignor to the American Electric Vehicle Company, same place. Filed June 18, 1897. Renewed Sept. 21, 1898.

613,594. Electrical Fuse-Wire Holder. William D. Packard, Warren, Ohio. Filed Sept. 29, 1897.

TELEPHONE AND TELEGRAPH.

The San Francisco *Report* in its issue of the 24th ult. says: "The four great telephone and telegraph systems of this coast will henceforth be known as the Pacific States Telephone Company. These companies are the Oregon Telephone & Telegraph Company, with lines covering the greater part of Oregon; the Inland Telephone & Telegraph Company, taking in Eastern Oregon and Washington; the Pacific Telephone & Telegraph Company, comprising the lines in the city and county of San Francisco; the Sunset Telephone & Telegraph Company, whose lines cover nearly all of California, the lower portion of Oregon and Eastern Washington. These four companies are under practically the same ownership and have the same officers and boards of directors, so far as the State laws under which they operate will permit. The new name has been adopted for the sake of convenience."

The city council of New Orleans has granted the People's Telephone Company permission to go ahead with the work of constructing its underground conductors. Vice-president Curtiss of the People's Company states that the work will be pushed as fast as money and labor can do it. He promises to give the people of New Orleans a first-class, up-to-date telephone system, as thorough and complete as any in the United States. He says: "Every telephone that we put in will be on the metallic circuit and prepared for long distance connections, and even the residence 'phones will have two wires, or, in other words, a wire going and returning, all to themselves. We will put but one subscriber on a line, because we do not believe we can give good service by putting three or four on a line, and what we want to do above all things is to give perfect service."

The Hon. John Roche, a member of the British Parliament, who is at present in Ottawa, expresses the opinion that by January 1 next the land telegraph line will be finished between Dawson City and Skaguay, and as soon as possible afterwards the latter place will be connected by cable with Vancouver. Mr. Roche represents a number of English capitalists who have acquired the charter granted by the Dominion Parliament last session to a company to build this line from the coast to Dawson by way of the Yukon and its affluents. The plan is to construct a double land line from Skaguay to Lake Tagish and Fort Selkirk to the Klondike, following the present mounted-police route, so that the police posts may be used as telegraph stations. Work is to be begun immediately.

The Grand Rapids, Mich., *Herald* of the 26th ult. says: "In the case of the Western Electric Company against the Citizens' Telephone Company and others, which was decided some time ago in the United States Circuit Court in favor of the defendants, proceedings have been perfected for an appeal to the United States Court of Appeals for the Sixth Circuit. The suit was based on alleged infringements of a device for making connections and calling customers to telephones by the insertion and rotation of a 'crank shaft' or 'spring jack' in the switchboard at the central station. The device is alleged to be covered by the Gilliland patent, which contention the telephone company disputed successfully in the lower court."

A Circuit Court jury in Kansas City decided recently that W. J. Meeker of Caney, Kan., was not libeled when, in 1895, J. W. Jordan of Cross, Ok., sent him a telegram saying: "Your sweet lies give you the advantage of me. Use it if you like and show who you are robbing. Pay your own messages." Meeker waited two years after the sending of the telegram and then went to Kansas City and sued the Western Union Telegraph Company for $2,000 damages to his reputation. The company proved that nobody could have known of the telegram aside from Meeker, Jordan and three operators.

The South Texas construction office of the Bell Telephone Company, located at Houston, has a great deal of work on hand at present. In a few days it will begin the construction of a new 111-mile toll line, leading from Corpus Christi to Victoria. The former place has so far been isolated from the telephone world. Complete plans have been made for a line from Texarkana through to Houston via Palestine, but these have yet to be approved by the company.

A delegation from the Merchants & Manufacturers' Board of Trade, New York, last week held a conference with representatives of the New York Telephone Company in regard to a reduction in rates. On behalf of the board the delegation asked that the company give to subscribers the rate of $50 for 1,000 calls or less, and five cents each for all calls above that number. The company's reply had not reached the board at its meeting on the 3d inst.

General A. W. Greely, Chief Signal Officer, says that up to the present time the work of improving the telegraph service in Porto Rico has been restricted to lines that were a military necessity. Offices in which only civil business is taken have been left to the last. In many of the offices the Spanish operators remain, in order that there may be no congestion of business through the ignorance of Spanish customs and language of the American operators. About one hundred men of the Signal Corps are now employed in this service, and with the introduction of American customs it is believed the number will be materially increased.

A project is on foot by G. M. Van Ausdall, J. E. Peterson and E. H. Stephenson of New London, Ia., and J. W. Gregg of Lowell, Ia., to place the two towns in communication by telephone. The enterprise will be organized immediately and the work of erecting the line will be pushed at once. The Lowell people have indicated their desire for such a service by purchasing a liberal supply of tickets which entitle them to the use of the line for a limited time. The public will be charged a reasonable fee for the telephone.

The Empire State Telephone Company has abandoned several of its lines in Ontario county, N. Y., and taken out the instruments from its offices in Bristol, Bristol Center, East Bloomfield, West Bloomfield, Bristol Springs, Naples, Honeoye, Reed Corners, Rushville, Miller's Corners, Middlesex and Vine Valley. This action was taken to avoid litigation with certain farm owners along the roads through which the company's poles are erected and wires strung, who were induced by a Batavia lawyer to sue the company for damages at the rate of $6 a pole.

The Washington *Star* states that Lieut. Col. Robert Craig, Signal Corps, United States Army, has been ordered to proceed to Santiago de Cuba and thence to Guantanamo, Baracoa and other points, in order to examine and report fully upon the extent and condition of the telegraph lines in the department of Santiago, the availability of timber supplies in the country for the reconstruction and other essential points connected with the reconstruction of such lines as are necessary for military purposes.

Honolulu, the capital of Hawaii, is a city numbering 30,000 inhabitants, and is lighted with electric light; it has a complete telephone system. The islands of Oahu, Kauai and Hawaii have telephones to every accessible point. The rent of an instrument is moderate, and a small charge for service is made for those who do not or can not afford to possess an instrument of their own. On the Island of Maui the telephone system is as yet incomplete.

The People's Telephone Company of Detroit, Mich., has declared a dividend of 10 per cent. In the last year the entire line was equipped with a metallic circuit. The company's lines are now connected with Wayne, Romulus, New Boston, Willow, Waltz, Carleton, Flat Rock, Rockwood and South Rockwood.

The York Telephone Company and the Pennsylvania Telephone Company are both endeavoring to get a foothold in Dover, Pa., but there is a company already in operation there, composed of local people, which opposes the entrance of either of the others into the town, and consequently Dover has become a center of telephone agitation.

The American Bell Telephone Company's instrument statement for the month ended October 20 shows: Gross output, 33,639; returned, 11,823; net output, 21,816. In the same month last year the gross output was 23,181; returned, 7,145; net output, 15,986. The total output October 20 was 1,077,402.

The Minnesota Central Telephone Company has extended its line into St. Paul and opened a station in that city for the convenience of the public. The lines connect with Ortonville, Appleton, Brown's Valley, Elbow Lake and the intermediate points on the lines on which these towns are located.

A telephone line from Sparta, Tenn., to Crossville is now assured. Manager J. N. Cox of the Gainesboro Telephone Company has let the contract for line material and the poles and wires will be erected in a short time.

At Norton, Kan., an automatic telephone system is being put in, and will be ready for operation by the middle of the month. About 75 'phones have been subscribed for.

In the recent fire at Tuskegee, Ala., the telephone exchange was among the thirteen business places totally destroyed.

New Company Incorporated.

The Fowler Switchboard & Telephone Company, New York—to manufacture telephone and other electrical fixtures. Capital stock, $5,000. Incorporators: John F. McKay, Samuel B. Fowler and Victor Heckles.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12⅜c.; Lake, 12½c.; casting, 12⅛@12¼c.

The Chicago Telephone Company declared a dividend of 1 per cent., payable November 5.

The West Chicago Street Railway Company has declared a quarterly dividend of 1½ per cent., payable November 15. Books reopen November 16.

The elections had a deterrent effect on the stock market, and there has been little or no change in the quotations of a week ago, Now that the battle is over more activity is looked for.

The North Hudson Light, Heat & Power Company of Hoboken, N. J., has filed a mortgage of $2,000,000 with the New Jersey Title Guarantee & Trust Company on its plant and fixtures. This is part of the proposed plan of reorganization.

Judge Ricks in the U. S. Circuit Court at Cleveland, O., has issued an order restraining the city from putting in force the ordinance providing for a four-cent fare on the street cars. The car companies intend to fight the matter in the courts.

The gross receipts of the Montreal Street Railway Company for the year ending September 30 were $1,471,939.65; operating expenses, $764,884.35; net earnings, $707,055.30; net income per cent. of capital, $13. Passengers carried, 35,353,036; transfers, 10,508,603.

The following Pittsburg, Pa., traction companies declared dividends payable November 7: The Duquesne Traction Company, dividend of 2 per cent.; the Pittsburg Traction Company, dividend of 3½ per cent., and the Central Traction Company, dividend of 1½ per cent. Books in each case reopen on the 15th inst.

Justice Pryor of the New York Supreme Court has appointed William B. Royce temporary receiver for the Middletown-Goshen Traction Company of Middletown, N. Y., on the application of the directors for a voluntary dissolution of the corporation. The company has a capital stock of $400,000 of which $200,000 has been paid in.

The Baltimore Traction Company has declared a final dividend of about 1½ per cent. This winds up the affairs of the company and distributes what was left of its assets after the absorption of the property by the Consolidated Railway, formed by merging the City & Suburban and the Traction companies. The dividend is payable to stock of record June 30, 1897.

An item from Philadelphia in the Boston "News Bureau" says: "The immediate scope of the people behind the $25,000,000 New York Gas & Electric Light, Heat & Power Company, among whom are Messrs. Widener, Elkins and Dolan, is to repeat in New York what they have done in Philadelphia. This scheme comprehends consolidating all the electric light business of Greater New York."

The actual sale of the controlling stock of the Nassau Railroad Company of Brooklyn, N. Y., by R. T. Wilson to Edward H. Harriman is reported, and it is thought to be the first step in the direction of the consolidation of the Brooklyn and Manhattan surface railroad companies, a combination that may also take in the Kings County Electric Light Company and probably the Brooklyn elevated roads. Roswell P. Flower and Anthony N. Brady are said to be back of the Nassau stock purchase.

The Brooklyn Elevated Railroad, the Union Elevated Railroad and the Seaside & Brooklyn Bridge Elevated Railroad are advertised to be sold under foreclosure at the Real Estate Exchange, Brooklyn, N. Y., to-morrow, November 10. After the sale the companies will be reorganized on a plan which provides for the issuance by a new company of $13,000,000 common stock, $5,000,000 non-cumulative 5 per cent. preferred stock, and a first mortgage for $16,000,000, bearing 4 per cent. interest till 1905, thereafter 5 per cent.

Judge Hallett, in the United States Circuit Court at Denver, Col., has entered decrees of foreclosure and sale against the Denver City Cable Company and the West End Street Railway Company in the suits brought by the Central Trust Company of New York on the ground of default in payment of interest on mortgages. Bonds were issued by the cable company to the amount of $4,000,000, and by the West End Company to nearly $500,000. Sanford C. Hinsdale, United States Commissioner, was named as special master in chancery to sell the two properties. He will advertise both sales in Denver and New York for thirty days.

The case of the old bondholders against the Somerset Railway Company, which has been pending in the courts for several years, has finally been decided by the United States Supreme Court in favor of the defendants. This confirms the title to the property in the present holders and establishes beyond question the validity of the $225,000 of bonds which were issued to pay for building the extension from North Anson, Me., to Bingham. The suit was originally brought by certain holders of the bonds who had refused to exchange them for stock in the corporation, claiming that the foreclosure was illegal and that the new corporation had no legal title to the road.

The Fair Haven & Westville Railroad Company and the New Haven Street Railway Company have been consolidated, the former company becoming the owner of all the properties of the latter. The Fair Haven & Westville Railroad Company was formerly capitalized at $900,000. The capital stock of the new company is now placed at the sum of $2,000,000. The Fair Haven & Westville Railroad Company pays the New Haven Street Railway Company for their new acquirement the sum of $500,000 in cash and $200,000 in bonds, making $700,000 in all. The $500,000 is to be raised by one year's notes at 4 per cent., and may be paid by further issue of stock by the company. The Fair Haven Company gives $900,000 of the new stock to its own stockholders.

A number of leading business men and capitalists of Baltimore are forming a stock company for development and improvement in Maryland, and it is likely that the company will be speedily incorporated. The banking house of Hambleton & Co. is financing the enterprise, and associated with the firm in it are some of the most conservative and leading men of Baltimore. The capital stock will, it is said, be between $1,000,000 and $2,000,000. The proposed company has a charter from the Legislature granting it extensive powers, which will enable it to buy, sell and deal in real and personal estate, to borrow and lend money, to acquire land and lay out towns, to subscribe and hold stock in manufacturing and other corporations, to erect, sell and lease buildings, to establish summer resorts, to construct and operate steam and electric railroads, telegraphs and telephones anywhere in the State of Maryland, subject to the approval of the county or city authorities, and to lay tracks upon streets and public highways anywhere in the State. It also confers the power to condemn property.

Advices from Cleveland, says the Philadelphia "Stockholder," state that it is reported that the "Little Consolidated," properly entitled the Cleveland City Railway, is about to absorb the Cleveland Electric Railway, known as the "Big Consolidated." Moreover, the Interurban Electric Railway, comprising the Akron Bedford & Cleveland, the Cleveland, Painesville & Eastern, the Lorain & Cleveland, and the Cleveland, Berea, Elyria & Oberlin, is to be included. Interests in the latter may turn out to be the dominating force of the entire outfit. Should the plan be consummated it will bring under single control about 286 miles of track, comprising the entire street railway system of Cleveland, and extending thence to Painesville on the east, Akron on the south, and Lorain and Oberlin on the west. All of it is electrically operated excepting 84 miles of the Cleveland City Railway, which is a cable road.

EDITORIAL NOTES.

Electricity from the Tides. That an immense amount of tidal power is daily allowed to run to waste in the vicinity of New York City has long been known, and some time ago in an editorial we attributed this fact to conservatism, or if not lack of progress, a slowness in availing ourselves of opportunities. Probably one of the principal reasons, however, why the power derivable from the tides in both the Hudson and East rivers has not as yet been made use of for generating electricity has been owing to the fact that machinery especially adapted to meet the peculiar exigencies and requirements of such work would have to be designed. The old form of tide wheel which was made use of years ago for the generating of power wherewith to grind grain and saw logs would naturally be uneconomical in operation and totally inadequate to the present demands, and no new form of tide wheel has as yet been placed on the market suitable for work of this nature owing undoubtedly to a lack of demand for such machinery. Another cause which has probably had considerable weight in preventing the utilization of the tides in the North and East rivers for power purposes, has been the knowledge that such an undertaking would entail an immense expenditure of money for rights and privileges as well as for a power plant, without a certainty of obtaining satisfactory results from an engineering and financial standpoint. However, if reports are to be believed, a company is at present being organized in New York City, with a capital of $1,000,000, to build and operate a tide-water plant, and the necessary steps are being taken toward the securing of the requisite franchises. The promoter of this undertaking is said to be Mr. Thomas Edison, Jr., who has likewise devised and drawn plans for all the necessary machinery. The plant if built will consist of two metal pipes 15 feet in diameter and 100 feet in length, located under water in the channel and mounted on a solid masonry foundation. These pipes are to be pivoted in the middle and made to act as walking-beams through an automatic device actuated by the water flowing through them. The ends of these pipe walking-beams, as they might be termed, will then be made to operate the piston rods of compressed air cylinders. The compressed air obtained in this way it is proposed to utilize for running triple expansion engines which will in turn operate dynamos. The plant will be reversible, that is, capable of operating whether the tide is running either in or out, and at high and low tides, during the time the water is practically stationary, compressed air will be drawn from a set of storage cylinders to keep the electrical machinery in continuous operation. Whether a plant of this description would work satisfactorily remains to be seen, although it is claimed that a somewhat similar tide water power station recently tried in California has proven very successful. One thing would seem certain however, and that is, that were such a plant erected and run in the vicinity of New York City, even assuming that it was capable of generating but 6,000 HP. for five hours a day, the saving in fuel over a steam plant would about pay the interest on the $1,000,000 invested.

* * *

The Result of Invention. It has often and truthfully been stated that coming events cast their shadows before, but it may well be wondered whether the founders of this Republic had any idea of the magnitude of the results that would accrue from the work which they started; it might truthfully be said that they builded better than they knew. The progress of this country has never been more marked than in the past twenty-five years, during which time we have advanced from fourth among the exporting nations of the world to the second place, for to day it is a well-known fact that we stand second only to Great Britain, and it is reasonably safe to assume that before another quarter of a century shall have rolled by we will have attained the front rank among the manufacturing nations of the world. It is of course also well known that the inventive genius with which the people of this country are endowed has been the principal means of placing us where we are to-day, and it is upon well-established facts in possession of the United States Patent Office that we are able to sustain our plea for second place. Probably no one recognizes this more clearly than Mr. A. P. Greeley, Assistant Commissioner of Patents, who recently delivered an interesting address on this subject.

Foreign statisticians have been quick to grasp the significance of the figures bearing on the export trade of the leading nations. They have seen the rapid and steady growth of the United States during the past twenty-five years, and they have been prompt in the institution of comparisons.

The increase in manufactures of this country since 1860 forms the most remarkable feature of our growth in exports, and Mr. Greeley is of the opinion that it is undoubtedly due to the improvements in machinery made through the practical application of patented inventions. The direct bearing which these patented inventions have upon the exports of manufactures is shown by taking certain classes of products and comparing their export values for 1898 with those of earlier years. Take for illustration the year 1873, when instruments and apparatus for

scientific purposes, including telephone and other electrical machinery, were not included among the exports of this country, yet the records for the past year show that $ 2,770,803 worth of this class of manufactures has been exported. Another comparison worthy of note may be found in the fact that from 1873 to 1898 a jump was made in the value of the exports of iron and steel and manufactures of the same from $13,645,027 to $70 367,527. Patented inventions or the product of patented machinery are responsible for the export of agricultural implements such as mowers and reapers, for until 1887 but little was done in this class of manufactures so far as exportation was concerned, and in fact no very extensive shipments had been made prior to the year 1891. The same is true of electrical apparatus and instruments, which at the present time have become important items of the export trade.

* * *

Wonders Never Cease.

The ending of the nineteenth century would certainly seem to be fertile in wonderful projects for the utilization of electricity, and the later developments, if they do nothing else, nourish the impression that the future has in store many surprises in electrical research. First, wireless telegraphy made its appearance and was shown to be practicable up to a certain distance and under suitable conditions. Next it was announced that a method of seeing by electricity had been devised, but although considerable has been written on the subject the exact method of accomplishing this wonderful feat has been kept more or less secret. But a few days ago the world was startled by the announcement that Mr. Tesla had taken out a patent for a method of transmitting electrical power through the upper regions of the atmosphere without wires. According to the inventor, his device could be made to revolutionize modern warfare, as by the simple turning of a crank a vessel miles away could be made to start, stop or move in any desired direction. This, it is claimed, would be accomplished by placing on the moving body, whether ship, wagon or balloon, special mechanical devices. As in all cases of startling announcements, the lay press has taken the subject up and published alleged interviews with Mr. Tesla, bearing on the subject, of a most extravagant nature.

That Mr. Tesla has taken out patents on inventions of great value, and that he has contributed materially in this way to the progress of the electrical industry, is not to be doubted, but it is to be deplored that when the time is ripe for announcing to the world a new discovery or invention, Mr. Tesla does not see fit to do so before a body of scientists working in the same field, who would be in a position to thoroughly appreciate the advantages and disadvantages of the new idea. Instead however of promulgating the discovery through the medium of some recognized scientific society, the sensational dailies have usually been the first to get hold of it and have published alleged interviews and illustrations that were apparently devised to astonish rather than explain. Under these circumstances it is not to be wondered at that men of science look upon an announcement of this kind in a skeptical manner to say the least.

For instance, Prof. Cyrus F. Brackett of Princeton University considers Mr. Tesla's invention as totally impracticable, and says:

"The shortest, most correct and most complete criticism which I can make in reference to this bold boast is that what is new about it is useless, while that which is useful had all been discovered by other scientists long before Tesla made this startling announcement. You will find the whole theory which he has applied in any up-to-date text book. What Tesla has done is simply to make theoretical application, which would prove to be absolutely ridiculous in practice, of inventions which had already been discovered.

"There is nothing new about this. The theory is perfect, but the application absurd. So throughout Tesla's whole elaborate scheme, the theory is not at fault, although there is nothing original about it, but the circumstances under which its application would be necessitated are such that the only result would be failure."

The following statement by Prof. Dolbear of Tufts College, which recently appeared in the New York *Herald*, comes very near to expressing our own views on this subject:

"This last so-called invention of Nikola Tesla's is a very pretentious affair, and it is so incredible that the story is not to be believed until the work is actually done. If Tesla said all that the *Herald* quotes him as saying, then his whole scheme and his manner of working is unintelligible to me. He even says that 'this power can be exerted at any distance by an agency of so delicate, so impalpable a quality, that I feel I am justified in predicting that the time will come when it can be called into action by the mere exercise of the human will.'

"That is getting a little outside of science, but you will notice that Tesla himself is only predicting that this will come true. There has been no accomplishment. He proposes to do great things, but he does not tell how he is going to do them, and he hasn't done them himself yet.

"The announcement is most amazing, and coming as it does from Tesla, scientists are all the more chary about accepting it. During the last six years he has made so many startling announcements and has performed so few of his promises that he is getting to be like the man who called 'Wolf! wolf!' until no one listened to him. Mr. Tesla has failed so often before that there is no call to believe these things until he really does them. Meantime we are all waiting with much patience and without solicitude. We will believe them when they are done."

Under the Searchlight.

Notes and Comments on Various Topics.

PROF. R. B. OWENS, the new professor in charge of the electrical department of McGill University, Montreal, is introducing a new feature which will be of great value not only to the students but will also confer great benefits upon the general public. This will be a standardizing laboratory. There will be a room devoted to high potential machinery where a voltage of 200 000 will be obtainable. There will be machines of the various types, and new types of high tension transformers and alternating current machinery are being installed.

* * *

RUDOLPH M. HUNTER of Philadelphia has invented, so it is said, an electrically operated telescope which if ever built will be many times more powerful than that in the Lick Observatory. The principal feature of Mr. Hunter's invention is an inclined spiral track on which runs an enormous truck supporting a focusing apparatus consisting of an immense concave mirror. In the center of this track a tall observation tower will be placed so designed that the upper portion may be either raised or lowered electrically. Mr. Hunter firmly believes that a telescope built according to his design would be 500 times more powerful than any now known.

* * *

THE new switchboard which we referred to a few weeks ago as about to be tried by the New York Telephone Company was put in service at Harlem on the morning of the 13th inst., and is said to have so far given satisfactory results. As we explained in our former item, the removal of the receiver from its hook lights a tiny electric lamp by the side of the telephone number on the switchboard. Likewise when connection has been made another lamp is automatically lit and remains lighted until the receiver is returned to its hook.

* * *

"ALL this political excitement recalls my brief career as a candidate," mused a citizen the other day who now limits his practical politics to voting. "I was living at the time in a district where the people had a good Congressman and most of them were in favor of keeping him. But, of course, there was a dissatisfaction, as there always is, and by an immense amount of hustling for three days and nights preceding the convention, I was nominated.

"My party had a good safe normal majority, but I knew that some of its members were out for revenge and we made things hum. There was but little time in which to do a great deal, for the old organization was lukewarm and I had to perfect another one. I kept the wires hot to all parts of the district, and I was never more pleased than when a bright operator from another city came to me with his advice. He urged me to send all my dispatches to my chief lieutenant in cipher. Then I could say just what I wanted to and the enemy would be none the wiser. He would handle the matter for me if I would just have a wire run into my headquarters. He arranged the cipher and used it with wonderful skill. All I had to do was to write what I wanted to send and he did the rest. I kept him at that key from morning till late at night, and he never complained. Indeed, he often suggested things that I had better explain and orders that I had better issue. Everything went on as though it were greased, and I was dead sure. But I was simply slaughtered. My operator was in the employ of the opposition. All it had to do was to check my moves. I was in debt up to my ears and was laughed at for the way I had been taken in. I went to work, got even with the world and was happy. I wouldn't run for President now if the salary was paid me in advance."

* * *

THE Spanish papers waste no words, according to the *Electrical Engineer*, London, whenever they have a chance to attack the stranger within or, for the matter of that, without their gates. It appears that recently the rain flooded the boxes on the mains of the electric lighting company and the light went out in the theaters. That was bad enough, but it also caused Egyptian darkness in the printing offices of the *Heraldo de Madrid*. Considering how badly Spanish papers are usually printed, we should say that they want all the light they could get to do it in. However, next morning a leader appeared, in which it was said: "Every time four drops of rain fall in Madrid the *magnificent* (the italics are the *Heraldo's*) installation of the English company shines out (?) conspicuously." After describing the damage done and bewailing the frequency of the occurrence, the Government is asked to look into the matter and to compel the company to lay its cables in a more efficient manner, especially as it had managed to formulate its contracts in such a way that no one could claim compensation for any damage caused by these frequent mistakes.

* * *

IN a recent report issued by the United States Geological Survey the production of copper during 1897 is given as 491,638,000 lbs., an increase of 7½ per cent. over the previous year.

New York Electrical Society.

Mr. E. H. Johnson will lecture before the New York Electrical Society on Thursday evening, November 17, at 8 P.M., at the College of the City of New York, Lexington avenue and 23d street, on "Surface Contact Railways, with special reference to the Johnson-Lundell System."

LONDON NOTES.

[From our London Correspondent.]

Northern Society of Electrical Engineers.

This Society has just opened its winter session at Manchester with an address by the president, Mr. J. S. Raworth, who took for his text "The rapid development of electrical engineering during the present year." He quoted as an instance of the great progress which is being made in electrical work in England the enormous increase in the capital invested in electrical companies. Mr. Raworth calculates that of every £100 applied to the purposes of electric lighting, £37 went to the manufacturer of plant—engines, boilers, dynamos, etc.—and £34 to the manufacturer of cables. A backward branch of electrical work is the propulsion of boats. There is only one active company on the Thames, but the speaker looked with confidence to the development of that branch in the future. Touching upon the distribution of power, the president said they were in the midst of a scheme which would commend itself not only to electricians and engineers, but to the country generally, as a most practical development; he referred to the Trafford Park scheme. That was an undertaking to supply power in bulk for driving and lighting all the factories, warming all the houses, and in fact doing everything that was necessary except the supply of education. The scheme would be but the nucleus of a very much larger development.

Mr. Raworth's most interesting remarks were made upon the use of American made electrical machinery for English works. He said that it was a very good thing that at present English electricians had the possibility of getting the plant they wanted from America, because were it not for that fact there was no doubt the development of electrical enterprise in England would now be suffering very great strangulation. So far as he could see, Americans were only supplying those orders which we could not execute in England. He hoped no one would lose heart by seeing plant coming into England, but that they would persuade their friends to subscribe to new companies coming out for the manufacture of things which they now had to purchase abroad.

Municipal Telephones.

There is every reason for believing that the granting of telephone licenses by the Postmaster General for the establishment of municipal telephone services is to be pretty general if Councils continue to apply for the necessary permission. We have already mentioned the granting of the Glasgow license. The Huddersfield municipality also has learned that a license will be granted, and Manchester is similarly placed. Judging by the expressions of feeling in many large towns, the desire is pretty general, but in all cases the licenses will only extend to December, 1912, when the National Telephone Company's powers lapse. The municipalities are in some cases wondering what will happen to them at that date. Parliament has yet to confirm the policy of the Postmaster-General. Manufacturers of telephone apparatus are naturally looking for some improvement in business if municipal exchanges are established.

Liverpool Electric Trams.

The Liverpool Corporation has recently completed its short experimental section of overhead trolley tramways at a cost of about £50,000. The line is not yet in actual operation, but the Corporation has resolved upon the equipment of another short section and is considering a proposed scheme for the preparation of 18¼ miles of existing track for electricity and the construction of 8½ miles of new system, also for electrical working. The cost of street works for these lines, exclusive of course of overhead or underground equipment, is put down at £91,250.

ELECTRICAL ALARMS.*

BY J. EBEL.

Considering the large variety of electrical apparatus designed for commercial or domestic purposes, one is impelled to the conclusion that there is hardly any article of such wide-spread and universal adoption as the electric trembling bell, but notwithstanding the enormous output of this particular article, its form and device has apparently, with a very few exceptions, undergone no material alteration from the original type.

Since the introduction of the dry battery, which has now reached a condition bordering upon perfection, a little more progress has been made with regard to the compactness, utility and convenience of a suitable combination of the alarm and battery. A general description of some improvements in this direction may afford considerable matter of interest to many of your readers.

Fig. 1 represents a standard pattern of electromagnet with armature hammer and break contact bracket. There is nothing particularly new in this combination, its novelty and merit resting solely upon the compactness and simplicity of its general arrangement, thus facilitating the rapidity and cheapness of manufacture. The electro-magnet is secured to a board by means of a screw and washer; two little projections being pressed into the wood

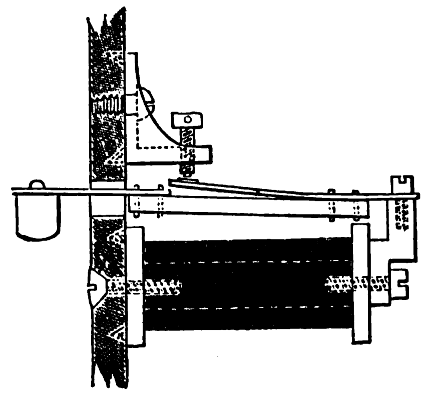

FIG. 1.

render it firmly secure. The hammer and contact spring are riveted to the armature and secured to the electro-magnet by means of a brass bracket and two screws.

The contact bracket, which is fitted with an adjustable contact screw, is secured to the woodwork as shown. This combination is condensed to the extent that it can be conveniently encompassed in the small space of 1 x 2.5 inches.

Fig. 2. is a section of a double alarm and battery combined, which consists of a portable case of dimension 6 x 6 x 3 inches, containing two Siemens dry cells, type O, sufficient space being allowed between these to accommodate two electro-magnets, whose hammers reach through suitable openings in the case placed in such a position that it enables them to strike the bells which are upon its exterior. The two bells differ from one another, both in size and pitch, which, since they are intended to work independently from the same battery, is necessary to form a marked distinction between them. It will also be evident that it can be arranged to work a single alarm.

Fig. 3 is a sectional view of another type of alarm known as the "Rattler." The principal feature attending this class lies in the fact that it is dust-proof and watertight. This device, with the exception that the bell is entirely dispensed with and a diaphragm substituted, is similar to the arrangement shown in Fig. 2; the electro-magnet hammer assumes a vertical position, and by its action strikes the diaphragm, which is so situated that the opening in the side of the case is completely covered by it on the interior, while the exterior side of the opening is covered by a sounding board which has a small hole in the center of it; the action of the hammer upon the diaphragm produces a strong vibration and a rattling noise from which the name of the apparatus is derived. From this description it will be observed that the case is securely closed in upon all sides.

Fig. 4 is a diagram of a burglar alarm. The usual principle of those in general use consists of

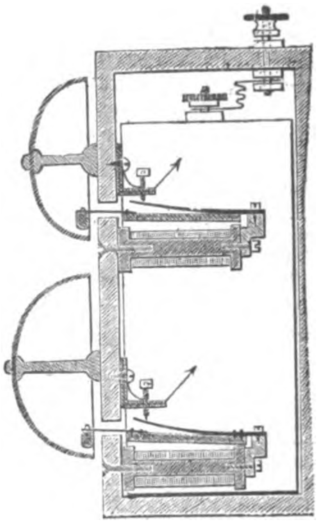

FIG. 2.

completing the circuit by means of opening or closing doors or windows to which contacts are fitted, and then connected up to the ordinary pushes, the bell ringing immediately the circuit is completed. The principle demonstrated by the accompanying diagram is, however, the reverse to the one described inasmuch that the alarm comes into operation immediately upon the circuit being broken; by this means a decided advantage is gained, because the slightest defect in the line through tampering, or any other reason, would at once be made known by the alarm, whereas in the former instance similar defects would render the apparatus useless for its designed purpose, and moreover, its defects could not be discovered without some trouble and testing.

The form of this apparatus resembles that of Fig. 1 or Fig 2, the only exception being that the electro-magnet solenoid is wound with two wires, one of a somewhat large dimension and having a resistance

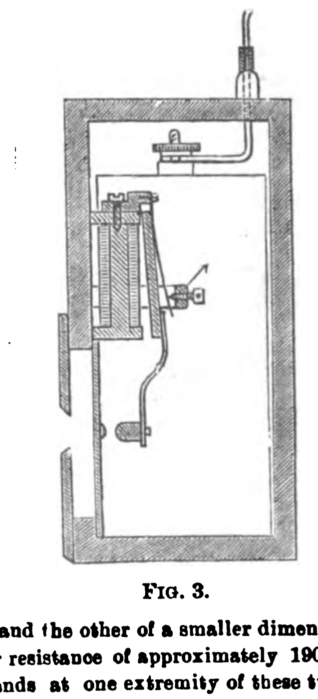

FIG. 3.

of 10 ω, and the other of a smaller dimension giving a higher resistance of approximately 190. The adjacent ends at one extremity of these two coils are joined together and permanently connected to the armature hammer or contact hammer, the other two ends by making an intermediate connection with the contact screw, C, are connected to the poles of the battery in such a manner that the current passing through the two coils would for each coil produce

* From the *Electrical Review*, London.

the same polarities on the extremities of the electro-magnet. The position X is the operating part in the out-going circuit, which operative effect can be arranged in numerous ways, i. e., by an opening contact spring attached to a flexible twin wire which is squeezed into the slot of the door, window or sash; this insertion falling out of its position when the door is opened, at once breaks the circuit and gives the desired result; again, the circuit between the points A B may be closed with a very fine wire,

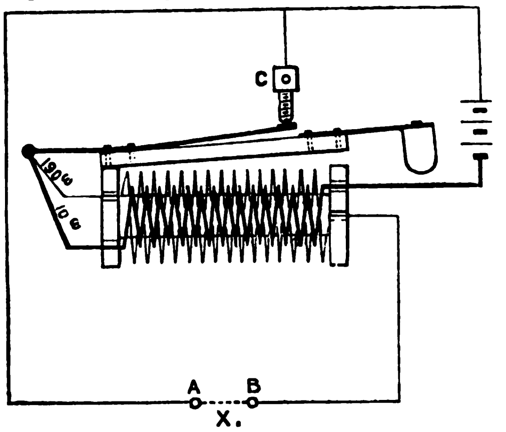

FIG 4.

almost invisible to the naked eye, and placed in any position where it is most likely to be broken; this affords a simple and expeditious method of obtaining the effect required, and which is explained as follows:

When the apparatus is adjusted for action the battery current passes through the two wire coils and forms a circuit. The electro-magnet with its highest resistance, which in this instance is 200ω becomes sufficiently excited to cause a slight descent of the armature from the contact screw, E, and thereby causes it to permanently maintain this pendulous position. The line being broken at X would cause the fine wire coil to be thrown out of the circuit, whereupon the circuit being now open, the armature would return to the contact stud, E, and thereby establish the make and break alarm circuit having only the thick wire coil retained.

Fig. 5 shows an entirely new form of electric alarm for very large sizes. Whereas the ordinary alarms working upon the "make and break" system are only satisfactory up to a limited size (say 6 inches diameter of bell), it is also obvious that the larger the alarm the greater must be the vibratory amplitude of the hammer taps, and the intervals of

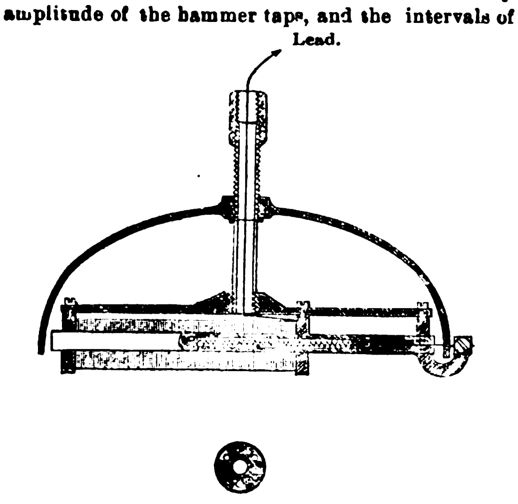

FIG. 5.
Top View enlarged of Brass Tube. Wrought-iron Core with steel balls.

proportionately longer duration, which result is practically unattainable by the present system, although it could be partly approached through the application of a larger electro magnet. This method, however, necessitates a larger battery power, and consequently produces the great disadvantage of excessive sparking at the points of contact, thus bringing about a rapid destruction of those parts, and furthermore, the make and break system cannot be worked either in series or in parallel, since each bell, for perfect working, requires its own circuit.

The section, Fig. 5, shows a solenoid wound round a brass tube, which contains an automatic, adjustable, hollow iron core. This core is provided with three longitudinal grooves for the accommodation of small steel balls, thus affording a practically frictionless longitudinal movement; the interior of the core contains a helical spring of suitable tension, having one of its extremities secured to the core, and the other attached to a fixed point situated as shown. The entire combination of parts is secured to a substantial bracket by means of screws, and by a piece of gas tube of suitable dimensions is suspended within the interior of a large gong or dome which forms a cover to the whole arrangement. The circuit is governed by an ordinary solid contact button or switch. When the circuit is open, the core, which answers the purpose of a hammer, assumes its normal position as shown, but immediately upon closing the circuit the core is drawn rapidly to the left and makes impact with that portion of the gong, and immediately upon breaking the circuit the recoil of the spring compels the core to produce another blow upon the opposite portion of the gong, i. e., to the right; thus it will be seen that action and reaction produce alternate blows, the rapidity of which may be varied "*ad lib*" according to the size of the gong. To especially adapt this gong for *continuous ringing*, I have conceived a device consisting of a combination of gear wheels and an escapement wheel in conjunction with a spiral spring and winding key. The contact is produced by a star wheel, the points of which form a rubbing contact with an insulated spring strip. For exceptionally large currents carbon contacts may be used with advantage.

The simplicity and compactness of this alarm renders it peculiarly adaptable for cheapness of manufacture. Its great reliability of action being largely due to the rubbing contacts being made at the *sending* station only, also another advantage is that any number of gongs may be worked in any circuit, whether they are in series or parallel. This apparatus is especially adapted to do duty for time bells in large factories, mines, etc., where a number of them could be worked from the timekeeper's office.

THE THOMPSON-WALKER CONTACT SYSTEM.*

The paper on contact systems of electric traction read by Prof. S. P. Thompson and Mr. Miles Walker at the British Association at Bristol serves as a fitting introduction to the above subject. We have, therefore, held back the paper till we should have had an opportunity of inspecting the line equipped by the authors in a private spot at Willesden. This we were able to see last Saturday, and a better day could not have been chosen for the experiment, as rain had fallen, and the whole track was saturated with water. After the description given in the foregoing paper, a further detailed account is not needed, and we shall here confine our attention to considering the advantages and disadvantages of the system. As certain untechnical papers have given badly-written accounts of interviews with Prof. S. P. Thompson, in which distorted views of the advantages are given to the public, we are sure Prof. Thompson will forgive us if we are rather critical in our judgment.

Mechanical Features.—The arrangement of the studs in the center of the track does not differ appreciably from that devised by other experts in contact lines. We are assured by these gentlemen that a projection of ⅜ in. for the surface of the contacts over the level of the roadway gives ample allowance for the contact shoe. This we rather doubted, and we found on Saturday that 1½ in. projection was allowed as a rule at Willesden. This is, in our opinion, the great objection to all contact systems, and the objection of course increases as the roadway wears down. This disadvantage has to be balanced against overhead wires with the trolley system, and against the open slot with the conduit, but we think that the open slot is much less objectionable.

Public Safety.—The arrangement of switch gear below the contact in the Thompson-Walker system gives decidedly greater safety against leaving a contact alive than any other contact system we know of. This is obtained by the use of the magnetic effect of the iron contact shoe on the car. Without a mass of iron is over the contact the switch is not closed even if the normal current is flowing through the shunt coil of the operating solenoid. It is equally true that the core of the solenoid falls directly the iron shoe leaves it and thus breaks the circuit. In the event of the shoe not making contact with the point it is approaching, the whole circuit is broken and the car stops. With other contact systems a failure of the incoming contact also stops the car; but, as a rule, it runs on sufficiently far to leave a live contact exposed behind it. This live contact is bad from the public's point of view, but it gives the tram driver a chance of getting his supply again, as he can do by hand that which the shoe under the car failed to do.

We experimented with a newspaper on Saturday, and found that when moistened and laid over a contact it several times held the shoe up for a sufficient length of time to break the circuit. We used a *Daily Mail* for the purpose, and pulled up the car three times out of five attempts. This experiment reveals a defect which will entail a somewhat expensive addition to the equipment of the cars run on the system. In order to re-establish connection, they will have to carry a battery of accumulators capable of giving 500 volts and a discharge of at least a quarter of an ampere. The current is not so much a difficulty as the fact that about 250 small cells and their connections must be kept in order. These can, of course, be charged from the main circuit, but it will not do to leave them always in parallel with motors. When the contact is lost, as will somewhat frequently occur in streets which are not well swept, the controller handles will have to be brought back to open circuit before the small battery is put on to pick up the connection to the main.

The Switch Gear.—The present form of switch gear used is very ingenious, but we do not believe that it will be satisfactory in extended practice. In the first place, mercury contacts are used, and they appear to be light for the current required in starting. Mercury contacts have given great trouble, even where readily accessible, and we are sure the inventors are wrong to put them in buried switches. The next point is the shunt coil, in which 500 volts are used. This is a high voltage for the primary current; and as it is often made and broken, the insulation required must be good. Dry oil must be used in the vessel to prevent the insulation depreciating. We entirely disagree with the statement in the pamphlet describing the system where it says: "The insulation for the winding of the magnet is most simple. It need only be of the most primitive kind, because the inner end of the winding is connected to the reel and the outer end to earth." There is another mis-statement in the pamphlet. It says: "When the plunger falls, it 'earths' the stud and blows the feeder fuse in case the stud has not been disconnected, thus affording, in any such event, absolute security against accident. This method of earthing is believed to be more reliable than anything which has hitherto been proposed, because it is dependent upon nothing but the action of gravity and the continuity of a stout earthing conductor."

Our readers after glancing at this extract will be

* From the *Electrical Engineer*, London, October 28.

surprised to hear that the reliable action is a myth. The stud is never earthed by a stout earthing conductor, as is stated, and if it was, the contact shoe would, by putting 500 volts direct to earth, blow every fuse in circuit. The plug is earthed through the high resistance of the shunt coil and the earth connection is not sufficiently good to give safety. This the inventors have endeavored to provide in other ways by preventing leakage currents to the idle studs.

Comparison with Other Systems.—Comparisons between contact systems and the trolley system are useless, as where the overhead wire can be used neither the conduit nor the surface-contact system can compete on account of the much higher capital cost and of the greater cost of upkeep. Our comparisons must therefore be confined to the conduit system. Leaving the question of price till later, there is no doubt that the well-designed conduit is better from an engineering point of view. The contact systems (not Prof. Thompson's in particular) require a large number of automatic switches in the roadway, say some 300 per mile, and the failure of either of these disorganizes the whole traffic for a few minutes at least, and piles up all the cars behind the fault. The next point is an electrical one. Prof. Thompson is represented by an evening paper of repute to say that his system will cause less electrolytic troubles to surrounding gas and water pipes than the conduit. This is quite incorrect, and we trust that the reporter is to blame. All modern conduits are being constructed with insulated return conductor, so that earthed return through the rails need not be used. In this respect the Thompson-Walker system is no better than the trolley system, and the rails will have to be most carefully bonded and provided with return feeders to prevent trouble.

A comparison of first cost is made by the inventors, which reads as follows:

COST PER MILE OF SINGLE TRACK.

I. *Overhead Wire System.*

Trolley wire and adjuncts	£300
Poles	£400 to 1,200
Permanent way and paving	3,500
Feeders	4,000
	£8,200 to 9,000

II. *Open Conduit System.*

Cost of conduit under favorable conditions, including conductor rails, insulators and drainage	£3 900
Permanent way and paving	3,500
Feeders	4,000
	£11,400

III. *Surface Contact System.*

180 to 360 boxes costing, say, £5 a-piece	£900 to 1,800
Permanent way and paving	3 500
Feeders and adjuncts	4,200
	£8,600 to £9,500

These last figures will not bear criticism. Thus, with the overhead system £300 is allowed for the trolley wire and adjuncts. On the surface-contact system this is reduced to £200, added on to the feeders. This small sum of £200 has to provide a mile of insulated conductors laid and jointed. The cable unjointed is likely to cost considerably more than £200. When it is considered that from 180 to 360 joints per mile have to be made, the total inadequacy of these figures is apparent. As regards the joint-boxes, these are not at present incorporated in the switch gear under the contacts, but may be in future. At any rate, the estimate includes nothing for this considerable item. The switch boxes themselves are put down at £5 each, and we see no reason why they should not be made for this, but judging from other electrical supplies there is little, if any, profit at this figure. As to how the development of the system is to be undertaken we know nothing, but it must be remembered that the inventors' royalties have to be capitalized and added to the corrected estimate. With this added, we think that the final price will not be appreciably cheaper than the conduit. As a system the line is interesting and shows that the inventor knows how to take advantage of the previous attempts in the same field, but we do not think that the conduit line has been improved upon, either from an electrical or mechanical point of view.

ELECTRIC LIGHTING AS APPLIED TO ARCHITECTURE.*

BY THOMAS EKIN.

I assume that in this year of grace it is unnecessary for me to take up your time by dwelling upon the manifold and very apparent advantage of electric lighting over every other form of illuminant, whether it be considered from a hygienic, artistic, decorative, or even commercial point of view, and it is generally admitted there are very few individuals—excepting, of course, those interested in gas or oil companies—who will not honestly endorse this statement. At the commencement of this paper, then, it will be as well to state that I do not propose to touch upon or refer to the subject of electric lighting outside buildings; that is, upon the generating plant or other sources from whence electric energy is brought into the building or group of buildings, but rather to confine my remarks to internal lighting and the manner in which the current should be conveyed to the various points of light.

Dealing firstly with the distribution of lights, it is obvious that the lighting of different classes of buildings requires distinctive treatment, because the lighting of a cathedral cannot be compared with that of a railway station any more than the lighting of a ballroom or drawing-room can be compared with that of a bedroom or kitchen. Each room or space which it is intended to light should be considered and examined from at least three different points of view, namely:

(1) The purpose for which it is to be used.

(2) The decorations, furniture and general surroundings, and

(3) The cost of the proposed lighting.

Which of these three points is the most important is probably a matter of opinion, but it may safely be assumed that the third point, or question of cost, is not the least important, because it may be taken as granted that the skill of the architect or engineer in arranging a system of lighting is in no case more marked or apparent than in getting the maximum lighting effect at minimum cost, this minimum cost including not only the first cost of putting in the work, but the more important one of annual expenditure and renewals.

When considering the question of lighting new buildings by electricity, the subject can be treated and dealt with with a far freer hand and, generally speaking, with far greater effect than in the case of houses at present lighted by gas or other form of illuminant, because one is so very apt to take the positions at present held or assigned to gas as those most suitable for electric lamps, quite forgetting the fact that gas is so non-adaptable and lends itself with such ill grace to artistic effect that there are only certain positions in any room in which it can safely be placed. Now I shall assume as an axiom that the most perfect form of lighting is that evolved from a hidden system of lamps—in other words, where no portion of the lamps themselves are brought in direct contact with the retina of the eye. It is, however, only right to point out that this form of lighting, like many other nice things in this world, is, generally speaking, the most expensive, because, as a rule, it means the placing of the lamp or lamps under some form of shade, whereby a large portion of the illuminating power is lost, and, therefore, and in order to get the same effect or amount of light from hidden lamps as from ordinary unshaded or only partly shaded lamps, double or even treble the amount of energy has to be used. In public halls, concert rooms, churches, etc., the points of light can, if taken from the ceiling or roof, be raised sufficiently far above the heads of the audience that, unless they wantonly gaze at the lamps, no inconvenience to the eyes need necessarily be felt, but it is different in the case of ordinary rooms, be they drawing-rooms, boudoirs or dining-rooms; and it is these classes of rooms which in my opinion require the most careful thought as to the disposition and arranging of the lamps.

In dealing with this matter, it is perhaps unnecessary to say that I am dealing solely and wholly with the incandescent electric lamp, and that I do not propose to touch upon the question of arc lighting this evening, because, though this light is pre-eminently suited for streets, railway stations, and other similar places, it is not, and I believe never will be, suitable in any way for the internal lighting of buildings. Many of you here this evening must, at some time or other, have been struck with what is generally termed the "glare" of the electric light, and possibly may have thought that this was one of the inherent faults of the system. I need hardly say it is nothing of the sort, and the fault lies, not in the system, but in the brain of the stupid person who put it there. No sane man or woman, with any regard to their eyes, willfully stares at the noonday sun; but I submit it is just as idiotic to put up a clear electric lamp and gaze at it as it is to gaze at the sun. Electricity, like most other things, to be properly appreciated must be suitably adapted to the end in view, which, as before stated, is a diffusion of soft light, without the lamp from which the light emanates being brought in direct contact with the eye. I am fully aware that the cost of complying with this requirement is in many cases too heavy to allow of its being adopted, but I submit there is no reason why every electric lamp should not in some form or other be shaded, even if the shading is simply the putting in of an "obscured" lamp in the place of a clear one. It is evident, or at any rate should be evident, that the lighting of each particular room or space should be separately considered, and that being so, it is impossible to lay down any hard-and-fast rules as to what is necessary in each particular case; and it requires a certain, or I may go even so far as to say a good deal of practical experience and judgment to know the proper amount of light required, and also the position in which the lamps should be placed. Under these circumstances, therefore, I fear it is quite impossible for me to lay down any rules which would be of the slightest value in enabling you to properly arrange for the lighting of any building in which you are interested. There are, as you are doubtless aware, certain "rule-of-thumb" rules which are given in pocket books and similar literature, but I have never found them to be of the slightest value, but, on the other hand, rather misleading. Take, for instance, a drawing-room. What use is it to any one to know that a 16 candle power lamp will light a certain number of square feet of floor when raised a given height above it. In my opinion none, for the simple reason that it is quite impossible to take into calculation or make due allowance for the surrounding coloring of either walls or furniture.

Leaving artistic effect out of the question for the moment, it is evident nothing is easier than to drop a number of pendants from the ceiling, and if these are kept a certain distance from the floor, you can procure the maximum amount of light with the minimum number of lamps and cost. This mode of lighting is, however, not to be recommended; indeed, it is strongly to be deprecated, and when one sees a room lighted in the above manner, it is at once apparent that a Goth, Vandal, or other barbarian has had the arranging of the lights. I think it will be generally conceded that the most pleasant, and at the same time most artistic, method of lighting ordinary living rooms is by means of wall brackets, standard lamps and table lamps, the lamp in each case being shaded so as not to come in direct contact with the eye. With regard to the other rooms in a house, there is not, as a rule, much diffi-

* Read at the October meeting of the Architectural Association.

culty in assigning the right position for the lamps and their numbers, but at the risk of reiteration I would again impress upon you the desirability of considering the lighting of each room, or at any rate of each principal room, separately, and from the three points of view mentioned at the beginning of this paper.

Now the next portion of my paper has to deal with the manner in which the electric current is brought from the place where it enters the building to the lamps themselves, in other words, that portion of the work generally spoken of under the comprehensive term "wiring." As you are doubtless aware, this word "wiring" includes not only the supplying and laying of the various wires and cables, but also—at least, as a general rule—the switch and fuse boards and subsidiary switches, and occasionally the necessary "cutting away and making good," this latter expression being in many cases incorrect, as you, like myself, have probably found by experience that it could be more accurately described as "hacking and tearing away and not making good." Many of you have doubtless had before you the bids of some electric lighting contractors for the lighting or wiring of certain buildings, and, perhaps, have even gone so far as to draw up a common specification on which these various firms have bid, and you have doubtless been surprised to find that the highest bid is sometimes half as much, and in some instances as much again as the lowest, and furthermore have been puzzled to know what should be done under the circumstances. Of course, if no specification has been issued, the reason of the difference in prices is easily explicable, inasmuch as the contractors, having no common basis upon which to draw up their bids, simply send in an estimate for the work and material they consider necessary, with the result that if the contractor is an honest man, taking proper pride in his work and with a reputation and good name to lose, his prices must be, and always are, considerably higher than those of an individual whose commercial instincts have unfortunately prevailed and got the better of his moral ones. It is far otherwise, however, if the contractors have estimated on a common specification, because if there are great discrepancies in the bid it is evident either that the individual quoting the lowest figure is willing to forego all profit or else that the one quoting the highest figure intends to make a fortune. Neither of these hypotheses is probable or ever likely to occur in practice, and it will generally be found that the real cause of the differences may be found in the loose and unscientific manner in which the specification has been drawn up. For a skilful and perhaps unscrupulous contractor nothing is easier than to drive a coach and four through a loosely and inaccurately drawn up specification, whilst it is evident that even an honest contractor—being but human—will avail himself of every opportunity in interpreting an ill-drawn clause to his own advantage. Perhaps I may be considered wanting in courtesy in suggesting that you are likely to draw up a faulty specification, but I can assure you nothing is further from my thoughts, and my only object in speaking thus plainly is to insist upon the absolute necessity of drawing up the specification in the most careful manner and with a full knowledge of all the requirements necessary and incidental to the proper carrying out of the work. My experience has been that many points of vital importance to the work are—probably from want of technical knowledge—entirely omitted from many specifications, and others of no technical importance are treated with a fulness and amplification entirely unnecessary. What is the use of carefully specifying the density of current allowed per square inch of sectional area in the copper conductor, when the loss of pressure, or, to use a more technical phrase, the fall in voltage, or electro-motive force, is omitted? None whatever, because in the case of a light or group of lights, placed at some distance away from the source of supply or point from whence the electric energy is brought into the house, the contractor might possibly be carrying out his work strictly in accordance with the specification and yet the lamp or lamps would look like "hot hairpins," owing to the fact that the very essential point of loss of pressure had not been taken into account. Again, what is the use of specifying the most heavily insulated wire and omitting the final test when the work is completed? Instances like these could be given ad libitum, but for the purpose of argument this is unnecessary.

There are still two points upon which I should like to give a warning, and these are, firstly, the low-priced contractor who looks to make his legitimate (or, as some would say, his illegitimate) profit on fittings, and, secondly, the contractor who offers to put in the work so that it will comply with the ridiculously low requirements—I refer to the test of the insulation resistance—of the fire offices. In London and other towns where there are electric supply companies, this latter danger is to a large extent rectified and guarded against by the fact that all work has to pass the more reasonable standard of the supply company, but it still remains in the cases of country houses, and houses in towns where the owner or occupier generates his own electric energy.

CONTROLLING APPARATUS IN CENTRAL STATIONS.*

BY R. DUNNING.

The arrangements for controlling the plant in central stations often leave a good deal to be desired. There are switches, valves, gauges, instruments, etc., all over the works, and in many cases there is not a man in the place, from the engineer downwards, who could tell straight off what each belonged to. Now, all the plant in a central station—engines, boilers, generators, steam and water pipes, pumps, etc.—should be considered as one complete machine, a machine for making electric light; and the engineer-in-charge should be able to tell how all the plant is working without having to run about the station. He should be able to feel the pulse of the station, as it were, from the switchboard, so that in case anything goes wrong he may see at once which item of the plant is in fault.

The great idea in a central station should be to make everything as plain as possible in order to lose no time in a breakdown, where every second may be of importance, and to this end everything should be arranged so that it is almost impossible for the men to make a mistake. They should not have to stop to think which is the right switch or valve, but should be able to decide at once.

The switches, of course, are a very important part of the controlling apparatus of a central station. They should all be placed near together so that the attendant can see what each machine is doing without having to move about. The switchboard should be placed near the wall at the center of the engine-room, and raised some feet above the floor in order that the attendant may see all the dynamos and signal to the engine-driver more easily. No one but the engineer and switch attendant should be allowed near the board on ordinary occasions. All the main machine switches ought to be placed on one board. They are generally arranged on panels. Each panel is numbered to correspond to a machine, and contains the switch, ammeter and main fuse for that machine, and the dynamos being numbered in large figures, easily seen from the switchboard, there is no fear of the wrong switch being opened or closed by mistake. In alternating-current stations the exciters should have a separate switchboard of their own close to the main board, with the switch gear arranged in the same way, and each switch numbered. This will be easier for the switch attendant than if the exciter switches were arranged on quite a different plan to the main ones. It is important that the attendant should know the speed at which the machines are running, and reliable speed indicators should therefore be attached to each, with the proper speed marked in red; but where alternators are run in parallel the best way is to have a good speed indicator fixed on the switchboard, or close to it, driven by a small synchronous motor supplied with current from the bus bars through a transformer, and as this motor will always rotate at the same speed as the alternators, and could be coupled direct to the speed indicator, it is a better arrangement than a separate indicator belted to each engine. It is a bad plan to have switches on or near the dynamos, as in case of a machine burning up it might be impossible to get at the switch; and besides, there is the danger of anyone passing the machine accidentally moving the switch. Of course, where the brushes have to be adjusted by hand, directly the machine is switched in, as in the case of the old open-coil arc machines, a switch on the machine does not matter so much—in fact, it is rather an advantage. All rheostats should be placed as near as possible to the switches they belong to, so that the attendant can adjust the resistance and at the same time watch the effect on the ammeter or voltmeter.

In order that the engineer may know the output of the electrical machinery and its behavior at any particular time recording instruments should be used; each feeder or circuit should be provided with a recording wattmeter at the station end; there should be a recording voltmeter connected to the main bus bars, and recording ammeters are very useful on circuits where a constant current is required. These recording instruments are of great use to the engineer; they show him how the plant will respond to a sudden increase of load, and also how the men in charge of the different parts of it attend to their duties, besides indicating the presence of faults in the circuits, etc. The switch attendant should know when he opens or closes a switch how and why the particular result follows, not only that a certain result does follow a certain movement of the switch, and for this reason a large diagram of the electrical connections should be hung on the wall near the switchboard. The diagram might be drawn on a piece of thin sheet-iron painted white, the more important connections being traced with different colored paints; it could thus be easily kept clean and alterations made when required. With a diagram of this description, combined with a card of emergency instructions, there should be little fear of a switch attendant making a mistake.

The engineer in charge of a central station should be provided with an office close to the switchboard and opening into the engine room, in order that he may be at hand if anything goes wrong. He should have a set of standard instruments for testing the ammeters, voltmeters, steam gauges, etc., in the station, besides a set of indicators and gear, thermometers, draught gauge, speed counter, etc., for testing engines and boilers. His office should be connected by telephone with the clerk's office and also with the different sub-stations, if sub-stations are used, if not with one or two call offices in the town in order that the lamp trimmers and men working on the mains may report to him when necessary. Telephones to different parts of the station are of very little use; if the engineer can sound a loud electric gong in the engine room and boiler house he will easily be able to give what few orders he requires by its use. Just outside the office a gauge should be fixed showing the steam pressure in the main steam pipe, another gauge showing the draught in the main flue, and others for vacuum, water pressure, etc., if necessary; these gauges may be recording instruments if it is desired to have a permanent record of the readings.

The steam and water valves are a very important part of the controlling apparatus of a central station, and great care should be exercised in their arrange-

* From the *Electrical Engineer*, London.

ment and use. All valves in the works, down to ½ in. drain valves, should be right-handed ones, as this prevents a great deal of confusion; they should be placed in easily accessible positions (in some stations valves are to be found in every out-of-the-way corner), every one numbered plainly, and in all but perfectly obvious cases they should have brass labels attached showing what they are and what they shut off. All valves ought to be opened and closed and the spindles oiled once a week, and once in six months or oftener the covers should be taken off and the valve seats examined, as it is most important that valves should be tight and at the same time work freely; and yet it is often the case that when a valve has to be closed very quickly, owing to the bursting of a steam or water pipe or something of that kind, it takes all the strength of two men to close it slowly, thus turning what might have been only a slight accident into a serious breakdown. The engineer should have a diagram in his office showing all the steam and water pipes in the works, with the positions of the valves, which should all be numbered to correspond with the actual ones. This will save a lot of trouble when valves require repairing, etc.

Automatic devices are of very little use in a central station; many have been tried and fresh ones are brought out every day, but the general experience seems to be that they cannot be depended upon for long, although they may work perfectly when new, as the action of rust, dust and dirt and wear is not taken sufficiently into account when designing these appliances. Besides this, the use of automatic machinery tends to make the men careless, as they get into the way of trusting too much to it and neglecting precautions which they would otherwise take.

These matters may seem very trivial, but they are really most important to the successful running of a station, and it would pay central station engineers well to spare no pains in order to make the controlling arrangements of their plant so simple that it would be almost impossible for a man to make a mistake even in the greatest hurry. At present the majority of central stations are behindhand in this respect, and what engineer is there who could walk round his plant and if he asked himself, "What would happen if I closed this valve or opened that switch?" could reply without any hesitation in every case? As far as the valves were concerned, he would probably find that he knew nothing about many of them.

AN ELECTRICALLY OPERATED DRAWBRIDGE.*

BY WALTER KIDDE, M. E.

Since February 22d of the present year there has been in successful operation a 450-ton drawbridge over the Passaic River at Newark, N. J. This is the largest electrically operated drawbridge yet constructed, and the consequent necessarily original designs, starting with the fixed requirements of the builders, are interesting.

The problem, as put to the contracting engineers having the installation of the motive power was, that they were to furnish, by means of electrical machinery, power (from a 500 volt direct circuit) which would open or close the bridge in 30 seconds, this power not to be available until the wedges and locking device had been withdrawn, also that the mechanism for operating these wedges and the closing bar be automatically cut off, so that they could not be used until the bridge was closed. Furthermore, a whistle for signaling purposes was to be ever ready for use; while, what is essential, the bridge was to be turned completely around and back and forth as the conditions of navigation required.

These conditions have all been met, and the bridge for the last five months has been successfully handled by three men on their regular trips, who, when they first went into service, knew nothing of electricity and little of machinery.

Two cables are led into the stream from one of the approaches and carried under the bed of the river into the center pier of the draw span. They are brought up through the center pin of the bridge into a contact commutator, all under the roadway. The commutator has two parts, the lower part consisting of a copper ring and a central copper disk on an insulator plate securely fastened to the stationary center bridge pin. Over this and acting as a cover is the part which moves with the draw. It is circular, of a heavy pattern, and has projecting through it on a diameter three copper plugs, also entirely insulated from one another and the iron box. Inside of the box these plugs broaden into shoes, two of which are held by means of springs to the center disk and to the ring of the stationary part respectively, and being constantly in contact with them establish a line and return to the motor room above. The third shoe intermittingly touches the lower ring only at times when the bridge is closed, breaking contact as soon as the bridge moves from this position. This is accomplished by two diametrically opposite cams on the lower insulated block, one of which, depending on the arc the bridge swings through, sets quick acting springs in motion to make or break this secondary circuit. The circuit uses the center plug as one of its poles and drives the motor when operating the wedge shaft.

Following these two circuits they are brought to the switchboard in the motor room with an automatic circuit breaker to properly safeguard the electrical machinery. The switches are usually kept closed as the controller and the switching table only are used in operating the motor.

The assembled machinery of the motor room consists of a motor with its shaft extended so as to carry the several clutches and gears arranged as follows:

First in order, there is the spur of a pair of gears which operates the line shaft for turning the bridge. This spur runs free on the shaft, being brought into action as part of same by means of a friction clutch. The shifter used in connection with this clutch serves also to throw in another smaller one controlling a sprocket wheel and chain to the shaft for the locking device and wedges.

The shifter oscillates between the two clutches as directed by a long operating lever. A motion to the right, besides mechanically gripping the large pulley with its system of gears for turning the bridge, closes the electrical connection corresponding to it on the switching table (in this case the main circuit). Thrown over to the left the lever makes the secondary circuit so that when brought well over it operates the wedge and drawing bar by throwing in the clutch controlling the wedge shaft. When in its central position neither clutch is in use. It is thus impossible to operate both clutches at the same time. The mechanism, which indicates the position of the wedges on a disk, is driven directly from the wedge shaft; it also interposes automatically a latch bar in the arc of the swinging lever. Thus in trying to turn the bridge after having locked it by moving in the wedges, the latch bar will hold the lever in that segment until the wedges have been withdrawn, when the bridge may be opened.

At the extreme end of the extended motor shaft is a sprocket wheel, connecting by means of iron link belting to a triplex, direct-acting air-pump which maintains a pressure of 40 pounds in a suitable air receiver used to operate the whistle for signaling purposes. This pump can be put in operation even while the operating lever is in its central position and all other machinery idle.

The speed of the motor and its direction of rotation is governed by a reversible controller having suitable resistances to control the speed of the motor when driving the different loads due to operating pump, wedges and bridge. The controller is placed near the main operating lever at the switching table so that the operator can manipulate the entire mechanism in one position, where windows have been placed so as to render visible the stream and the movements of vessels.

The drawbridge structure is 720 feet long, while the draw proper is 227 feet in length and 67 feet wide. The total weight of the moving span is 450 tons.

Current for the motor is furnished by a line from the People's Light & Power Company of Newark, whose station is a few hundred yards above the bridge on the river.

It may not be amiss to point out the possibilities in the electrical operation of drawbridges. Over the Harlem River in New York City there are a score of bridges, one close upon the other. They could all be operated and lighted from one central plant with closely regulating high speed automatic engines, radiating power which would precede a ship in its passage through the successive draws.

* From the "Stevens Indicator."

HULL MUNICIPAL ELECTRIC SUPPLY WORKS.*

As announced in our issue of last week, the electric supply works of the Hull Corporation have recently undergone considerable extension, in the opening of a new generating station at Sculcoates-lane. The history of the electric light undertaking in Hull is briefly as follows: In 1887 an electric lighting committee of the Corporation was formed, and on August 4 of the following year an electric lighting order was obtained. Mr. R. E. Crompton was engaged to report on a scheme, and recommended, in 1891, a low-pressure scheme at an estimated cost of £16,000. This was followed by the appointment of Mr. F. Harman Lewis as borough electrical engineer, the Crompton scheme being immediately proceeded with. This scheme included a generating station in Dagger-lane, with engines aggregating 560 HP., direct coupled to Siemens dynamos of 300 kilowatts capacity. The original plant included accumulators of the Crompton-Howell type, and about 2½ miles of mains laid on the Crompton system. On June 16, 1893, these works were opened and have since run continuously with complete success. There were 33 consumers connected at the time of the inauguration and an equivalent of 600 lamps. During this year considerable extensions of mains took place, about three miles of mains on the Callender-Webber system being laid. In the following year the plant at the Dagger-lane station was extended by the installation of a 300 HP. Willans engine and a 180 kilowatt dynamo, and in the next year a similar extension of plant took place.

Owing to the rapidly increasing demand for current, it became necessary, in June, 1896, to consider a scheme for very extensive additions to the electrical supply system, this scheme being estimated to cost £42,000. Unfortunately, it was twice rejected by the Town Council, but in December of the following year Mr. Hammond's report on the scheme was submitted for a third time, and finally accepted by the Council, with the addition of £10,000 to the estimate for the district of East Hull. At this time the number of consumers connected was 520 and the capacity of the plant 26,817 lamps. No less than 340,339 units were sold during the year 1896, a profit of £1,970 being made on the year's working. The new works were pushed on with, but owing to some delay in starting them and to the increased number of applications for current, temporary works had to be laid down in 1897, these commencing supply in conjunction with the Dagger-lane station. The temporary works ran from November 5th until March 5th following, when the capacity of the Dagger-lane station was increased to 1,160 HP. in engines and 660 kilowatts in dynamos. The present capacity

* Abstract from the *Electrician*, London.

of the new station in Sculcoates-lane, together with the sub-stations at Argyle street and Albion street is 760 HP. in engines and 456 kilowatts in dynamos, but there are 750 HP. in engines at present under order together with 450 kilowatts in dynamos. At the present date there are 863 consumers connected to the mains, and lamp connections aggregate 67,900 while no less than 16½ miles of mains have been laid including the 3¼ miles now actually being laid. The customers include a great variety of consumers, there being, in addition to the ordinary lighting consumers, a fairly large motor load for printing and other work. We will now proceed briefly to describe the equipment of the new station and the sub-stations which have been recently erected.

Boiler Room.—In the boiler room there are at present erected two Lancashire boilers, each being 30 ft. in length and 8 ft. in diameter, together with a Babcock-Wilcox boiler of 150 HP. The last named boiler has 1,218 sq. ft. of heating space, composed of six sections, each section having nine tubes 4 in. diameter and 18 ft. long. The headers are made of wrought steel and the drums are 36 in. diameter and 23 ft. 7 in. long. The boilers work at 150 lb. pressure. All the boilers are at present hand fired with the best South Yorkshire steam coal. In conjunction with the boiler plant there is a Green's economizer, composed of 192 tubes, arranged in two groups, coupled together by expansion elbows and tested to 350 lb. pressure. The feed pumps are of the direct-acting vertical type, with the pump underneath. They throw their supply from a tank filled with softened water, a water softener of the Pemberton type being used, together with a clarifying or filtering tank and apparatus for thoroughly mixing the reagent solution with the water to be softened. The feed supply is arranged on the duplicate ring main system, similar to that employed for the steam ranges, and arranged so that any pump can supply any boiler either with cold or hot water. In addition to the feed pumps there is also an independent injector feeding gear, which can be used either in conjunction with the pumps or otherwise. The water for the feed, as well as for the condensing plant, is pumped out of an adjacent drain by means of two centrifugal pumps 5 in. and 7 in. in diameter, and is discharged into a large overhead tank of 29,120 gallons capacity. Each pump is driven independently by an electric motor. From this tank the water is supplied to the two ejector condensers through a 12 in. pipe. The exhaust from the engines can be turned either into the condensers or into an atmosphere pipe of 15 in. diameter which runs along under the floor and is carried upwards outside the building. The steam ring consists of two parallel lines of 8 in. wrought iron solid drawn pipe, with welded flanges resting on cast-iron chairs behind and above the boilers and connected at the ends with copper U bends of the same size as the pipe. Into this ring each boiler feeds by a separate copper pipe bent into an S shape so as to avoid strains due to expansion. The standpipes are each provided with a complete set of valves enabling each boiler to be used independently, an arrangement which is also applied to the engines running off the ring mains. The plane of the ring is inclined downwards towards the boilers and it is drained at two points by steam traps. One 30 B.H.P., and one 14 B.H.P. shunt motor have been erected, coupled to centrifugal pumps for condensing purposes; also one 2 B.H.P. shunt motor for driving the economizer scrapers, all the motors running off the 220 volt circuit.

Machinery Room.—In the machinery room there is erected high and low pressure continuous-current plant, having an aggregate capacity at present of 456 kilowatts. The low-pressure plant consists of two Willans engines of the G. G. S. type, each indicating 100 HP. under 140 lb. steam pressure. These engines run at 450 revolutions, and are coupled direct to two-pole dynamos, each dynamo giving 130 amperes at 300 volts. These machines are for the supply of local consumers, also for the pump and economizer motors on the works. The motor generator is also installed in the building, and is used for balancing purposes or for supplying light loads in conjunction with the battery. The high-pressure plant consists of two Willans engines of the I. I. I. S. type, capable of developing 360 HP. at the same pressure when running at 350 revolutions per minute. These are coupled direct to two-pole dynamos, each giving 90 amperes at 2,250 volts. These generators are separately excited from a 225 volt circuit. The armatures of these machines are wound on the Eickemeyer principle. All the engines are fitted with Messrs. Willans and Robinson's automatic expansion gear and a separate condenser is provided for each engine, the condensers being of the Körting injector pattern, and arrangements are made so that each set can be run either condensing or non-condensing, as required. A 10 ton hand-power traveling crane spans the engine room.

Switchboards.—The switchboard equipment consists of two separate switchboards for the high and low pressure plant respectively. These have been made as nearly as possible fireproof, being composed of 1½ in. slate slabs mounted on iron frameworks. The low-tension board contains two dynamo panels, one battery panel, two feeder panels, one Board of Trade panel, one motor-generator panel, and one works distribution panel. Each dynamo panel is fitted with a Weston ammeter and voltmeter, a D. P. switch with maximum and minimum control, a throw-over main switch and field regulating switches. The battery is placed on one side of the three-wire system and 18 regulating cells are connected to the switchboard. All motors, lights, etc., on the works are connected to throw-over switches on the works distribution panel, so as to enable them to be run from either side of the system. Wattmeters are installed in the low-tension feeders both here and at the sub-stations, so that all current delivered to the distributing mains is metered.

The high-tension switchboard contains two dynamo panels, one Board of Trade panel and six feeder panels, and four spare panels for extensions are provided. Each dynamo panel contains a Weston ammeter, a Kelvin voltmeter, a D. P. switch with maximum and minimum control, and field regulating switches. The dynamos are connected by the D. P. switches to the high-tension 'bus bars, from which the feeders are tapped. The feeder panels each contain a Weston ammeter and voltmeter, a D. P. switch with maximum cut-out, and transformer starting and regulating switches. The voltmeters on the feeder panels are connected to the feeding points on the low-tension mains, and the pilot wires are connected to them via the shunt coil of a long range switch on each transformer. By short-circuiting the voltmeter about 5 amperes is made to pass through this coil, and the long range switch is actuated, connecting a transformer to that particular feeding point. A repetition of the process throws the switch into the "off" position.

Battery Room.—The battery room at the main station contains 126 Pritchett and Gold 11-plate cells in glass boxes. The capacity of this battery is 300 ampere-hours at 225 volts.

Sub-Stations.—There are at present 2 sub-stations, one at Albion street and one at Argyle street. The building at Albion street was specially designed for the purpose, and contains two 90 kilowatt rotatory transformers and a motor generator. Room for an extension of the plant is provided. At Argyle street four railway arches have been utilized, two of which are used as stores for the outdoor department, one as a battery room and one as a transformer chamber. In the battery arch there are 240 Pritchett and Gold cells similar to those at the generating works. These are charged in three sets of 80 cells off the distributing mains, and are discharged in two sets of 120 cells. The switchboard is situated in the transformer arch, where there are two 90 kilowatt and two 45 kilowatt machines with the necessary switches, etc. The 90 kilowatt transformers are wound for a step-down from 2,250 to 450 volts. The 90 kilowatt transformers at Albion street supply a portion of the old network and are wound for 2,250 to 225 volts, the motor generator forming a connecting link between the old 220 volt three-wire and the new 440 volt three-wire networks. The transformer armatures are provided with high and low tension winding on the same core and with a commutator at each end. They are "Eickemeyer" wound, with an earthed metallic shield between high and low tension windings. The lubrication is effected by a force pump on each bearing, and the machines can be run for long periods without attention.

Mains.—The mains extensions consist of six high-tension circuits running from the generating station in Sculcoates-lane to the two sub-stations and low-tension feeders running from the generating station and these sub-stations to various points in an extensive network of distributing mains. The high-tension feeders, pilot and telephone wires are drawn into stoneware conduits. These conduits are made in 3 ft. lengths, and are jointed together by means of stoneware cradles with Portland cement; no less than 45,000 yards of 2¼ in. by 2¼ in. duct has been used, spare ways being provided for future extensions. Draw-boxes built of 9 in. brickwork on concrete foundations are provided at all corners and bends and where otherwise necessary, and they are provided with cast-iron frames and covers and are ventilated by means of a stoneware pipe connected to a small ventilator frame. The high-tension feeders (of which about 17,000 yards have been laid) are 0.06 sq. in. and 0.03 sq. in. sectional area, concentric, insulated with impregnated fibrous material, lead-covered and externally taped and compounded. The low-tension feeders consist of about 4,600 yards of 0.5 sq. in. concentric lead-covered cable, armored with two layers of 0.05 in. hoop-iron and laid direct in the ground. Three 9 and 12 core pilot wires are laid alongside the feeders, and a four conductor "dry-core" (air space) telephone cable permits of communication between the generating and sub stations.

About 24,000 yards of distributors have been laid of the triple core, impregnated fiber insulated lead-covered and armored type, the positive and negative conductors being of 0.15 sq. in. section. The advantages of this class of distributing main for three-wire systems are now universally recognized. It combines flexibility with facility of jointing, the service and other boxes employed being of a much simpler construction than those for triple concentric mains.

All the cables, before and after laying, have been subjected to exhaustive tests with satisfactory results. The straight joints are made in cast-iron boxes in two halves bolted together. The internal fittings consist of copper sleeves and sockets for sweating the conductors into, and are embedded in the hard-setting insulating compound with which the boxes are filled. About 60 disconnecting boxes, both of three-way and four-way patterns, have been inserted in the network, and allow of any section of the distributor being rapidly cut out or disconnected for testing purposes. The internal fittings of these boxes are so arranged that either disconnecting copper links or fuses can be used. They are set in brick pits, with manhole frames and covers of similar construction to the draw boxes. The service cables are of the twin pattern, india-rubber insulated, lead-covered and armored, and are connected to the mains through cast-iron T boxes.

Measuring Line Losses.

Mr. F. Lecomte, says the *Electrical Engineer*, London, describes in *L'Electricien* a method of accurately ascertaining the fall of potential in a line or circuit in which there is frequent alteration in pressure.

This method consists in having two voltmeters, one at each end of the line. The circuit is then interrupted at the generator end. The voltage is read at that end at the time of break, and the observer at the further end of the line takes the interruption as a signal to record the reading on his voltmeter. The method is simple, but the necessary interruption is the faulty part of the idea.

TELEGRAPHS AND TELEPHONES IN PERSIA.*

The first telegraph line in Persia was established about thirty-six years ago, and in the beginning was vigorously denounced and opposed by the priests as being a species of magic and closely allied to other evil principles greatly subversive of religion and the best interests of the State, and as such not to be permitted to have a place in the economy of government. This opposition, however, was overcome and the class which resisted so stoutly at the first now use the telegraph with the greatest indifference. In the year 1862 the construction of a telegraph line from India to England through Persia, Russia and Germany was commenced, and it began working on January 1, 1870. Some work had, however, been carried on for three or four years by a line through the Euphrates Valley; but according to the United States Vice-Consul at Teheran, this was not by any means of a satisfactory character, and serious errors, delays and interruptions occurred. This line is still used occasionally.

The Indo-European is a well constructed and efficiently managed line. From Bushire to Karachi there is both a cable and a land line. This line provides the local native administration with one wire which can always be depended upon. The local lines, with the exception of the one wire mentioned above, are the property of the Persian Government. The ownership was acquired by the cost of construction, and has been maintained by defraying the expenses of preservation. The actual administration is deputed to one man, who, until very recently, contributed to the Government $12,000 a year. This royalty has now been raised to $30,000 a year. The yearly receipts of the telegraphs have been about $60,000, and the expenditure equals, if not exceeds, the income. In consequence, certain reforms are to be initiated in the direction of compulsory payments. It is stated that fully 50 per cent. of the telegrams are sent free. Officials of the Government (central and local), priests, expounders of the law, relatives of persons connected with the working and the administration, and everyone who can provide himself with a reason or excuse, send their telegrams free of expense. As this system has been growing for many years past, and most of those who have been benefited by it are in a position to give trouble, the management find it difficult to introduce changes necessary for their own protection.

The Persian local system comprises about 3,100 miles of wire and 86 offices for the receipt and despatch of messages. The wire provided by the Indo-European administration, gratis, is about 1,300 miles long, and extends from the Persian Gulf to the Russian frontier. Stamps are not used for any purposes in Persia except for letters. Messages are restricted to 10 words, at a charge of 2½ krans (about 18 cents). The actual charge for the message is 2 krans, and the half kran is for the paper on which it is written. In case the message extends to a large number of words it is calculated at the rate of 10 words to the 2 krans, and not 2½ krans. This tariff is the same for any distance in Persia; there is only one charge. The Persian newspapers rarely contain information of sufficient importance to be sent by telegraph, consequently there is no press rate, and, indeed, there are very few press messages.

There are four newspapers in Persia, printed in the vernacular, and under Government control. These should be issued once a fortnight, but they are often issued at longer intervals; they are in no sense considered as leaders or exponents of the ideas or feelings of the people. As regards telephones the late Nasredin Shah, on December 8, 1889, granted to the then Minister of Foreign Affairs a concession for electric lighting, the introduction of telephones, phonographs and the application of electricity to industrial purposes to the whole of Persia, with protection to the monopoly for the period of 60 years. This concession was transferred to an American citizen for a certain valuable consideration, but for want of means the purposes of the concession have not been put into execution. In order to protect the concession from lapsing, two or three wires were put up and kept in a workable state, and are now in use.

Five years ago the railway and tramway company commenced erecting private wires for anyone who would undertake the expense, and they established an exchange office on their own premises at Teheran. It has not been extended to any other town. So far no records have been kept of the number of miles of wire erected, but the Vice Consul says that from his observation he should estimate it at about 50 miles—this is including the wires into villages of summer resort, and those to different parts of the city. At the present time there are 15 owners of private wires, each of whom pays the company about $2.12 per month for keeping the wires in repair and the instruments in order. The receipts about balance the expenditure, but this only includes the free use of the lines by the company, who provide the only office there is in the city and two in the country during the summer months. As messages are not received from the public no tariff has been formulated. Subscribers are put into communication and use the telephones as long as they wish. As a more extended use of the telephone would interfere with the receipts of the telegraphs, permission to use it has not been granted to distances appropriated by the telegraphs.

Motor Car Trials in Paris.

In the competition of motor-cars for heavy loads, which took place in Paris from October 6th to 12th, the electrically propelled cars did not gain any distinction. Of the four electric cars competing, only one went through all the six journeys prescribed as tests. These journeys were, however, of such a nature as to be particularly trying to electrical automobiles, being on three routes—26, 29 and 41 miles long respectively—with one minute's rest after each kilometer traversed. It is intended, according to the *Engineer*, to choose a special route for the electric cars next year, to fulfil as much as possible the conditions of town and suburban goods transport. The Jenatzy van of the Compagnie Général des Transports Automobiles is of the same system as the cab which took part in the recent Paris trials, except that it has no change-speed gear. The gross weight was 4,500 kg., including 1,500 kg. of dead weight and four passengers. The batteries of Fulmen accumulators weigh 1,200 kg. and the inventor claims that with these the van can run 120 km. With a discharge of 28 to 30 amperes the vehicle ran 12 to 13 km. an hour on the level, and on the up grades the discharge was 70 amperes and the speed 7 km. an hour. The average voltage was 82. The van accomplished all six routes without incident.

The Société des Electromobiles presented a van upon the Bersey system with a battery of Fulmen accumulators. It completed five out of six journeys. The Krieger van was not ready before Monday, so that it was only able to cover the three routes once. As with nearly all the French electric cars, the energy was stored in batteries of Fulmen accumulators. The weight of the vehicle was 2,500 kg., including 600 kg. of dead weight. On the A route the average rate of discharge was 24 amperes at 85 and 86 volts, and the consumption was 6 kilowatt hours. The carriage work of the Mildé Mondos van is, says our contemporary, of the highest class description, and is fitted with a duplex motor, the power being transmitted by chain from a very small pinion on the countershaft to the rear driving wheel. There were two batteries, one containing Mildé accumulators and the other Fulmen; moreover, one of the batteries was old and the other new. To make matters worse, the accumulators polarized through bad charging, and for most of the time the van was in the tent undergoing repairs.

The only time it finished a route it was followed by a portable engine with a dynamo, and this precaution was a wise one, for the batteries had to be re-charged on the road to enable the van to return to Versailles. The greatest interest was taken in the trials by delegates from local bodies all over the country, and the Minister of War ordered a large number of officers to follow them with a view to ascertaining whether motor cars could be profitably employed for military purposes.

Trolley Sickness.

Trolley sickness, says the New York *Sun*, is causing great distress in the northern suburbs and in parts of Brooklyn. As is well known, young children are usually exempt from seasickness, but they enjoy no such immunity in the matter of trolley sickness. On the contrary, they are peculiarly the victims of this new disease. As infants play around in careless glee on shipboard, while their wretched elders are lost to the world in their bunks below, bent in abject misery over the rail or stretched limp and listless upon blanketed steamer chairs, so on the trolley cars, while grown folks swing merrily from the overhead straps, or bawl the latest gossip into one another's ears, the poor little victims of trolley sickness writhe in tortures and wail in unison.

In the case of trolley sickness, as in that of sea sickness, fresh air is often the best remedy, and so it happened that so long as open cars were run upon the suburban trolley lines infant misery was kept within reasonable bounds. But now that the advance of the season has brought out the closed cars, the sickness daily increases. It must be remembered, too, that in the case of trolley sickness there is no such convenient rushing to the rail as in the case of sudden seizure on shipboard. To be sure, most unhappy looking infant faces are daily seen protruding from the windows of the trolley cars, but this convenient resource is seldom available, since trolley cars are so densely crowded much of the time that to get a child suddenly upon the seat and its head out of the window is almost impossible. Mothers of foresight encourage their children to stand on the seats and look out of the windows, so as to be in the very best possible position for any sudden emergency.

But when a trolley car is packed, as Brooklyn and suburban trolley cars sometimes are packed, and as horse cars never were packed, because no two horses could ever have drawn such loads, the position of the infant suddenly seized with trolley sickness is truly pitiable. So, too, is that of the mother, for she receives, instead of sympathy, the angry looks of her fellow passengers, who would flee her and hers as a pestilence, but who, struggle as they may and tread down and elbow one another as they will, cannot put more than six inches between themselves and the object of their disgust.

In Brooklyn, where the art of trolley-car riding has been brought to a higher degree of perfection than elsewhere, save in Philadelphia, there is a rumor that the trolley parlor cars at least are to have a corps of chambermaids. This provision, the managers of the trolley lines hope, will promote general comfort. Meanwhile there is a widespread demand throughout all the territory threaded by the Huckleberry lines for a remedy that will at least assuage the violence of trolley sickness, and a disposition among the childless to demand that the discrimination against children practised in some apartment and boarding houses be extended to the trolley cars.

EXPORTS OF ELECTRICAL MATERIAL FROM THE PORT OF NEW YORK.

The following are exports of electrical material from the port of New York for the week ending November 7:

Antwerp—4 cases electrical material, $2,821; 10 packages electrical machinery, $600.

Africa—3 cases electrical material, $457.

Argentine Republic—114 cases electrical material, $5,957; 30 cases electrical machinery, $2,781; 1 case electros, $2.

Brazil—2 cases electrical material, $110.

British Possessions in Africa—4 cases electrical material, $146.

Bremen—8 cases electrical material, $500.

British Guiana—8 packages electrical material, $359.

British West Indies—186 cases electrical material, $16,867.

Cork—4 cases electrical machinery, $166.

Cuba—44 cases electrical material, $1,159.

Central America—16 cases electrical material, $285.

Chili—15 cases electrical material, $189.

Dutch West Indies—3 cases electrical material, $37.

Dresden—2 packages electrical material, $27.

Ecuador—6 cases electrical material, $125.

Glasgow—8 packages electrical material, $856; 4 cases electrical machinery, $123.

Hong Kong—11 cases electrical material, $714.

Japan—2 electric motors, $79).

London—184 cases electrical material, $7,200; 21 cases electrical machinery, $1,560; 1 case electros, $117.

Liverpool—12 packages electrical machinery, $220; 12 cases electrical material $291.

Mexico—17 cases electrical material, $792; 5 cases electrical material, $50.

Newfoundland—6 packages electrical material, $58.

Nova Scotia—1 package electrical material, $24.

Newcastle—16 packages electrical material, $25.

Odessa—29 cases electrical material, $916.

Peru—21 cases electrical material, $387; 3 cases electrical machinery, $400.

Porto Rico—60 packages electrical material, $1,304.

Rotterdam—1 case electrical machinery, $300.

Siam—27 packages electrical material, $700.

Santo Domingo—8 cases electrical material, $75.

Southampton—8 cases electrical material, $628.

Uruguay—1 case electrical machinery, $739; 8 cases electrical material, $202.

U. S. Colombia—44 packages electrical material, $1,134; 8 cases electrical machinery, $704.

Venezuela—2 packages electrical material, $27; 7 cases electrical material, $80.

A Treasury Ruling on the Exportation of Incandescent Lamps.

On a question concerning the exportation of incandescent lamps, the following decision has been promulgated by the Treasury Department at Washington:

"On the exportation of incandescent electric lamps, manufactured by the Edison General Electric Company of Schenectady, N. Y., in part from imported glass bulbs and tubing, a drawback will be allowed equal in amount to the duty on such imported materials used in the manufacture, less the legal deduction of 1 per cent. The entry under which the merchandise is to be inspected and laden must show the marks and numbers of the shipping packages, and the number of lamps in each package, describing the bulbs used as they are described in the import invoice. The drawback entry must show the number of lamps of each kind or description exported, and must further show, in addition to the usual averments, that the said lamps were manufactured and packed for shipment in the manner set forth in the manufacturer's sworn statement, dated May 25, 1898, filed with the Collector of Customs at New York. In the liquidation of entries, 1,000 glass bulbs and 5 pounds of glass tubing shall be taken as bases of allowance of drawback for each 1,000 lamps exported. Samples may be taken, as ordered, by the collector, for such official examination as may be deemed necessary."

LEGAL NOTES.

The Seneca Electric Light and Power Company, embracing the plants at Seneca Falls and Waterloo, N. Y., has been placed in the hands of H. H. Crowell of Syracuse as receiver. The action was brought by the Old Colony Trust Company of Boston as trustee of the company's bonds.

The Colfax Electric Railway at Denver, Col., is to be sold by order of the court, on petition of George E. Ross-Lewin, the trustee. The face value of the bonds is $150,000, but the interest brings the indebtedness up to $216,000.

At New Orleans on the 3d inst., Warren B. Reed and Brainard Rorison, complainants in the case of Warren B. Reed et al. vs. Edison Electric Light Company, amended their original bill for a restraining order as follows: "That Warren B. Reed was the original and first inventor of the new and useful improvement for electric motors patented June 4, 1894, and the invention was not known or used by others here prior to his original invention, nor had it been used in this country for more than two years prior to his application for letters patent; and that Warren B. Reed and Edward Rorison are the sole owners of said invention and letters patent and of all rights and claims thereunder."

The Appellate Division has affirmed the judgment of the Supreme Court awarding $7,500 damages to Rose Flaherty for injuries resulting from shock from a fallen trolley wire of the Nassau Electric Railway Company at East New York and Rockaway avenues, Brooklyn, N. Y., on October 10, 1896.

The ruling of Judge Comstock in a recent street railway suit at Terre Haute, Ind., was as follows: "1. A street car company is not liable for damages caused by a horse taking fright at one of its cars when running along the street in the usual and ordinary manner, unless the motorman knew that the horse would become unmanageable if the car were not stopped and wantonly continued on his way, and it is shown that the accident could have been averted had he stopped the car after he had reason to believe danger from the fright of the horse was imminent. 2. A motorman who sees the driver of a horse dismount and hold the horse by its bridle as his car approaches may reasonably infer that such driver can control the horse while the street car passes. 3. The liability of a company for accidents of this kind arises only from unusual and improper running of cars or from conduct evincing a wanton disregard of the safety of persons known to be in peril."

CANADIAN NOTES.

A by-law to provide $6,000 for the purchase of an electric light plant for the town of Acton, Ont., has received the sanction of the ratepayers. Arrangements will be made immediately for the installation of the plant.

In the city of Halifax, Nova Scotia, a special committee has been obtaining information as to the advisability of the city undertaking its own street lighting and as a result the city electrician and engineer have been instructed to prepare plans and invite tenders for a suitable plant.

The most startling offer for the supply of electric power yet made in the city of Toronto was among the tenders received by the Board of Control of that city this week. A company has put in a tender to light the city streets and supply energy for manufacturing purposes at the rate of 1 cent per horse-power per hour. Their capital, they state, will be $5,000,000, and when their dividends reach 10 per cent. they offer to light the streets at cost price. They will also establish a manufactory for electric supplies and the profits of this will come under the same agreement.

Within another year Quebec, it is said, will be one of the best lighted cities in the world. It will have no less than three companies converting water powers in the vicinity into electricity. They will be the Montmorency Falls Company, the Chaudiere Company, now in course of formation, and the Jacques Cartier Water Power Company, which has already commenced to build at the falls of Jacques Cartier river in Valcartier, some 18 miles from the city of Quebec. This company will also build large pulp and paper mills at the falls.

The official announcement has been made by the Quebec, Montmorency & Charlevoix Electric Railway Company that it is proposed to electrify the road running to Cape Tourmente, Que., and to construct an independent branch to Montmorency Falls. The estimated cost of improvements is given as $330,000, and when completed the system will comprise over sixty miles of electric railway. The president of the company is H. J. Beemer.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING.

Camden, N. J.—The council has granted a franchise to the Citizens' Light, Heat & Power Company. The new company will bid on the street lighting contract as a competitor of the Camden Lighting & Heating Company, which has had a monopoly in the lighting business for several years.

Carthage, Mo.—The city council has passed an ordinance authorizing a special election on the 22d inst. to get a vote on the proposition to issue $25,000 in bonds to build and equip an electric lighting plant for public and private purposes. It is expected that the bond issue will carry. When built, the plant will include arc and incandescent lights.

Grand Rapids, Mich.—There is lively competition among the makers of lamps to see which company shall get the contract for furnishing the arc lamps for the new electric lighting system. The Adams-Bagnall lamp is named in the contract, but the Chase Construction Company, which is to install the plant, has agreed to furnish whichever lamp the board of public works decides upon.

Green Bay, Wis.—The Green Bay Gas & Electric Light Company and the Fox River Lighting Company have consolidated and the new concern will submit bids for the city lighting. The city is given the option of buying the consolidated plant within a certain time at the inventory price of the plants.

Grand Forks, N. D.—The East Side city council have decided upon municipal ownership of waterworks and an electric light plant. The recorder has been instructed to advertise for bids to be opened December 1. The plans and specifications submitted by W. J. Gray & Co., of Minneapolis, were adopted.

Iowa City, Ia.—The committee appointed by council to investigate the probable cost of erecting and maintaining an electric lighting plant in this city have made their report, in which after presenting the results of their investigations they think it advisable for the city, rather than build a plant, to enter into a five years' contract with the local electric lighting company at the rate of $70 per arc light per annum.

Lonaconing, Md.—The agitation for another electric light plant for this town continues, and if arrangements cannot be made with the parties putting in an ice plant here to combine a lighting plant with it, an independent lighting plant will be established.

Park City, Utah.—The Ontario Silver Mining Company, R. C. Chambers superintendent, has been granted a 25-year franchise to operate an electric plant in this city and to furnish light, heat and power by electricity to the public.

Savannah, Ga.—An ordinance has been introduced in the city council which is to give the Edison Electric Illuminating Company the use of the streets for the purpose of constructing an overhead and underground electric system to supply light and power.

Seattle, Wash.—Bids for city lighting were opened on the 1st inst. The bids were as follows: Union Electric Company—Arc lights, each, per month, $8 80; 15 candle-power, incandescents, each, per month, $1.32; 30 candle-power, each, per month, $1 95. Consumers' Electric Company—Arc lights, $9; 15 candle power incandescents, $1.40; 30 candle-power, $2.10, and for additional lights, arc, $8.75; 15 candle-power, $1.30; 30 candle-power, $1.90. The Seattle Gas & Electric Company offered to put in 100 sixty candle-power Welsbach lights at $2 per month. The Snoqualmie Falls Power Company offered to furnish arc lights in the First, Fourth, Fifth and Sixth wards, as now distributed, at $7 per month. All bids were referred to the secretary of the board for classification and comparison.

Talladega, Ala.—Two of our prominent business men will put in an electric lighting plant here if satisfactory arrangements can be made with the city authorities.

Trenton, N. J.—It has been officially announced that the controlling stock of the Trenton Light & Power Company is to be transferred shortly to Col. A. R. Kuser and Thomas C. Barr of Newark. It is also said that the shareholders of common or preferred stock are to have the opportunity of selling their interest at the same figures secured by James Moses, from whom the control was purchased. The "Gazette" says that those who are in a position to know say the move means that

the Delaware River Improvement Company is to come into Trenton, and that operations towards permanently establishing that corporation in this section are soon to be begun.

Watervliet, N. Y.—Preparations are being made to illuminate the public buildings with incandescent electric lights. At present the police station, corporation hall, chamberlain's office, office of the board of education and the several houses of the fire department are lighted with gas. It is expected the places mentioned will use the incandescent system of illumination before the close of the present year.

STREET RAILWAYS.

Bethlehem, Pa.—The formal opening of the Easton, Palmer & Bethlehem Electric Railway took place on the 10th inst. The ceremony was attended by the city officials of Easton, the borough officials of the Bethlehems, officials of the Allentown Traction and the Easton Transit Companies, a number of Boston capitalists and about twenty-five newspaper men. After a ride over the whole system a banquet was held at the American House in this city, where covers were laid for 100. The new railway is twelve miles long and connects the Bethlehems, Butztown, Farmersville and Altonah with the county capital. There is now a continuous electric railway from Easton to Siegfried's, a distance of thirty miles.

El Paso, Tex.—The city council has granted to a citizens committee the franchise for an electric street railway on the principal streets and for electric lights. The committee will transfer the franchise to capitalists who will establish the railway system.

Hagerstown, Md.—The directors of the Blue Ridge Electric Railway Company have selected a committee of prominent business men and experts to decide upon a route for the electric railway over the Blue Ridge Mountains. It is stated that the plan most likely to be adopted will connect Penmar and Blue Mountain House and then swing over to Blue Ridge Summit, Monterey, Buena Vista and back again to Penmar. From the latter point a line will extend to Waynesboro, Pa., and other points in the Cumberland Valley. It may also be extended to Gettysburg. The company is composed of Pennsylvania and Maryland capitalists.

Lexington, Va.—John R. Williams, a prominent business man of Richmond and owner of a large hotel in the western suburbs of Lexington, is considering the feasibility of building an electric road to the hotel, and has had an engineer examining the ground for the best route.

Lynchburg, Va.—The situation of affairs in Lynchburg in regard to street railroads is somewhat remarkable. About a month ago the city council granted a new franchise to the Lynchburg Electric Railway & Light Company, and gave them the right to extend their line into a new and large section of the city which has heretofore, to a great extent, been one of the chief contributors to the Rivermont Street Railway Company. Later the council granted the Rivermont Street Railway Company the right to extend a branch line from down town out to the city park, which will split the territory of the Lynchburg Electric Railway Company directly in two. When the two lines, as proposed, are completed, Lynchburg will have as complete a street-car system as any city of similar size in the country. The Rivermont line is operated by Lynchburg capital, while the other line is owned by New Yorkers.

Madison, Ind.—It is reported here that Benj. Johnson, the engineer who built the Madison street electric railway, has been engaged by Enoch H. Fudge and other Chicago capitalists to examine into the feasibility of constructing an electric railway from Lexington, on the Baltimore & Ohio Railroad, through Hanover and Madison to Vevay, a distance of forty miles.

Middleboro, Mass.—Articles of association have been formed for another street railway to connect the New Bedford, Middleboro & Brockton line, through Lakeville and East Taunton, with Taunton. It will be known as the Taunton & Middleboro Street Railway Company, with a capital stock of \$55,000. The route selected will lessen the distance from New Bedford to Taunton about four miles, while increasing the distance from Middleboro about two miles. The Taunton & Middleboro road will open up the lake country of the towns of Middleboro and Lakeville.

Neenah, Wis.—The Fox River Valley Interurban Electric Railway is completed and the first car went over the line a few days ago. The continuation of the road to Oshkosh is likely to cause another fight, the route being in dispute.

Newport News, Va.—The Peninsula Railway Company proposes to build an electric road connecting this city with Hampton and has applied to the councils of both places for a franchise. The company was chartered by the last Legislature.

Rome, N. Y.—The highway commissioner has granted right of way over the highway from Oriskany to Rome to the Utica Suburban Railway Company. The company will endeavor to get a franchise within the city limits.

Willimantic, Conn.—The Willimantic Street Railway Company has been organized under an arrangement made between Jesse W. Starr, representing a syndicate, and the original incorporators, for the purchase of the franchise which confers the right to the streets of Willimantic for the operation of a trolley railway. Mr. Starr agrees to put the engineers at work at once.

MANUFACTURING, ETC.

Cleveland, O.—Superintendent Charles A. Boyd, of the Walker Manufacturing Company, is reported in the "Cleveland Press" as saying: "Electricity will completely supplant steam as a motive power in less than ten years. We are to-day building electrical power devices that two years ago were not conceived. If the knowledge of electricity and new methods of using this mysterious power advances in the next decade as it has done in the last, steam locomotives and factories operated by steam power will be curiosities."

Harrison, N. J.—The General Electric Company have taken steps toward the erection of a much larger building on the site of their old lamp factory in this town. The new building will be 63 feet wide, and will have a floor space of 60,480 square feet. The contracts are about to be awarded and the cost of the building will be about \$75,000. The structure is to be finished by April 1, 1899. The output of the present works is said to be 40,000 incandescent lamps a day. The capacity of the new works will, it is estimated, be 50,000 a day.

Washington, D. C.—Consul Lyon writes to the State Department from Hiogo, Japan, that he has received a letter from the president of the Kobe Electric Light Company at that port, in answer to the consul's inquiries relative to electric light supplies. The company, the letter states, formerly used only the Edison lamp, but in 1894 changed to English and German lamps, in consequence of their being cheaper; but it recognizes the superiority of the American or Edison lamp, and says that as it is desirable to use lamps requiring the least amount of power, machinery for testing lamps is now being put up, which when done may disclose that it should discard the cheaper English and German lamps, and again use the Edison. The prices are given as follows: Lamps of 5, 8, 10, 16 and 24 candles, 32 sen (16 cents) apiece; 32 and 50 candles, 50 sen (25 cents), this being the cost on delivery at Kobe.

TRANSMISSION PLANTS.

Idaho Springs, Col.—A. R. Specht of Boston, who has built a concentrating mill at Dumont, is contemplating the erection of a big electrical power plant at that place to be run by the waters of Clear Creek, which are to be stored in two reservoirs, one to be constructed just below Lawson and the other between the town of Empire and the railroad. Wires will be run to most of the mines in that section and electric machinery of all kinds, including electric drills, will be installed.

Portland, Ore.—The water power of the Sandy River is to be utilized for transmission electrically to Portland and other points if surveyors who have been looking over the ground make a favorable report to Eastern capitalists who are said to be interested in the scheme. The Sandy is a very crooked stream of water, and is about 40 miles long. It drains one of the slopes of Mount Hood, and it has a habit of becoming a torrent at times, when its usual volume is tenfold larger than ordinary. Then it is that the water goes foaming and roaring to the Columbia, sweeping aside all obstacles. It will be a great engineering feat to build a dam to control the water when it becomes a torrent.

Toronto, Can.—The Ontario Government takes the view that the Niagara Power Company has forfeited its charter because of its failure to develop 10,000 horse power by the 1st of November, and will ask the courts for a decision on the question. The company's legal adviser says, as reported in the "Mail-Empire" "that \$100,000 had been spent on plant at Niagara Falls. Enough power had been developed to supply any reasonable demand eight times over, but there had been no call for it from local industries. The company had a demand for 8,000 horse-power from Toronto, and was perfectly willing to transmit to that city or anywhere else, if a few months' delay was granted. The great difficulty had been that there were no means by which power of any considerable quantity could be transmitted for a distance of 50 miles. That obstacle had now been overcome, and the company was now able and willing to transmit 10,000 horse-power if desired."

Victoria, B. C.—The Cascade Water, Power & Light Company now has an engineer upon the ground at Cascade City, preparatory to building a dam and developing the magnificent power at that place. Mr. Anderson, who superintended the construction and development of the Bonnington Falls power, has full charge of construction. It is contemplated putting in dam, flumes, etc., this winter, ready for the machinery, which will be put in place in the early spring.

COMPANY MATTERS.

Lowville, N. Y.—The Wetmore Company, which is building a transmission plant at Belfort, on Beaver River, has purchased the Lowville Electric Light & Power Company's interests.

Philadelphia.—The American Electric Meter Company, incorporated under the laws of New Jersey, has made an assignment for the benefit of creditors to William D. Marks, president of the company.

MINES, ETC.

Las Vegas, N. M.—An electric light plant is being put in place at the Confidence mine in the Mogollon district, and the machinery will hereafter be run and the mine lighted by electricity. One hundred and fifty men are employed.

PERSONAL AND MISCELLANEA.

A daily paper states that Col. John Jacob Astor has applied for a patent for an electric railway motor of his invention which he hopes soon to be able to test practically.

Sherman Gates, of Wichita, Kan., has been sent by a New York firm to Perth, Australia, to superintend "the electric mechanical construction of mining courts," and the Wichita "Beacon" states that he will be gone four years, with a splendid salary and all expenses paid.

The municipality of Paris has recognized the value of electro-therapeutics by adding a new wing to the hospital at La Saltpetriere, which will be devoted exclusively to the treatment of diseases by means of electricity in its various forms. While charlatans and quacks by their ignorant use of electricity have brought electro-therapy into disrepute, there is now a growing tendency among the medical profession to acknowledge that electricity has a well-defined place in the curative art.

"A few years ago," says the Hartford (Conn.) "Times," "the New London Street Railway Company inaugurated the plan of appealing to the employes to use all possible care in running the cars and all civility in the treatment of passengers, and in return offered the civility on its own part of a share in the profits, provided the employes responded to the suggestion. The plan has worked apparently to the satisfaction of all concerned. The road has just sent out notices to each of its employes that a certain sum of money has been placed to his credit in a savings bank on account of this extra compensation. This circular also expresses the thanks of the company for the services rendered, speaks of the 'faithful and intelligent performance of duty' by the men and mentions the advantage to the road, its patrons and its employes that attends giving the best service possible. We have not seen any mention of the amount of profits thus shared, but it is evidently enough to be worth some little additional care, and it certainly seems to smooth relations between the parties to the agreement. In the city of Norwich, sixteen miles away, it is proposed to inaugurate the same system before long, perhaps as early as next January."

Dispatches received in Chicago from San Francisco announce the death there on the night of the 2d inst. of C. H. Summers, chief electrician of the Western Union Telegraph Company. He was suddenly seized with heart failure and died in a few minutes after the attack. Mr. Summers entered the telegraph service in 1854 as an operator on the old Pittsburg, Cincinnati & Louisville telegraph lines, of which James D. Reid was superintendent. After this line was consolidated with the Western Union Telegraph Company he worked at different points as an operator, and in 1859 while working at Indianapolis was offered and accepted a good position on the railroad lines. Indianapolis was his headquarters until 1867, when he was made superintendent of telegraph of the Indianapolis, Cincinnati & Lafayette Railroad telegraph lines and located at Cincinnati. In 1869 he was called to Chicago as chief electrician of the western division of the Western Union Telegraph Company by Gen. Anson Stager. He had been in the service of this company as electrician ever since that time.

RECENT COMPANY ELECTIONS.

Haverhill, Georgetown and Danvers Street Railway Company, Haverhill, Mass.—President, Charles E. Barnes; treasurer, James F. Shaw; assistant treasurer, George A. Butman; clerk and counsel, Edmund B. Fuller; directors: Charles E. Barnes and John F. Hall of Plymouth, F. E. Lowe of Greenfield, James F. Shaw of Newburyport, George A. Butman of Malden, Arthur D. Veasey and Herbert B. Newton of Haverhill.

Merchantville Light, Heat & Power Company, Merchantville, N. J.—Directors: F. A. Downes, F. J. Burr, W. H. McCallum, George P. Williams, F. C. Robbins and William M. Griffith.

Montreal Street Railway Company, Montreal, Can.—Directors (all re-elected): L. J. Forget, James Ross, R. B. Angus, K. W. Blackwell, F. C. Henshaw.

West Philadelphia Passenger Railway Company, Philadelphia, Pa.—President, George D. Widener; secretary and treasurer, Alexander Renwick; directors: P. A. B. Widener, William L. Elkins, Joseph E. Gillingham, Geo. D. Widener, Thomas Dolan, James McManes, Joseph B. Altemus, Thomas J. Yarrow and George W. Elkins.

COMMERCIAL PARAGRAPH.

The Fostoria Incandescent Lamp Company of Fostoria, Ohio, announces that it has opened an Eastern office in the White Building, 95-97 Liberty street, New York City. This will also be the Eastern office of the Orouse-Tremaine Carbon Company.

INCORPORATIONS.

The Caro Light & Power Company, Caro, Mich. Capital stock, \$25,000.

The Rocky Ford Electric Light Company, Pueblo, Col. Capital stock, \$15,000.

The United Traction Company, Chicago. Capital stock, \$500,000. Incorporators: Albert E. Wilson, Anson E. Meanon and Louis J. Boham.

The Pacific Trading Company, Tacoma, Wash.—to conduct a general wholesale and retail brokerage and commission business, to erect and run factories, build and operate telegraph and telephone lines, electric light and

power plants, etc. Capital stock, $5,000. Incorporators: J. W. Garvin, F. H. Chandler and C. McDaniels.

The Harper's Ferry Electric Light & Power Company, Harper's Ferry, Va. Capital stock, $15,000. Attorney, D. B. Gibson, Charlestown, W. Va.

The Jackson County Electric Railway Company, Kansas City, Mo. Capital stock, $70,000. Incorporators: F. W. Sears, Annie G. Lightner, J. J. Hoover and others.

The El Porte Zuelo Light & Power Company, Chicago. Capital stock, $500,000. Incorporators: Chester T. Crandall, William M. Carpenter and William B. Patterson.

The Sawyer Manufacturing Company, Camden, N. J.—to manufacture gas and electric fixtures, etc. Capital stock, $50,000. Incorporators: H. H. Sawyer and H. S. Sawyer, Ridley Park, Pa.; Albert Bumm, Camden, N. J.; George L. Rowland, Philadelphia, Pa.

The Mitchell Pearson Electric Company, Portland, Me.—to manufacture and sell electric car appliances. Capital stock, $150,000, of which $25 is paid in. President, George A. Copeland, Revere, Mass.; treasurer, William E. Pearson, Winthrop, Mass.

ELECTRICAL PATENT RECORD.

Letters Patent Issued November 8, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

613,708. Electric Railway. James F. McLaughlin, Philadelphia, Pa. Filed May 2, 1896.

613,713. Trolley-Pole Guide-Rope. Samuel R. Parks, Central Falls, R. I. Filed Aug. 4, 1897.

613,744. Mechanism for Holding Trolleys to Their Wires. William R. Weaver, Covington, Ky., assignor of two-thirds to George L. Weaver and Harry D. Weaver, same place, and James C. Brown, Franklin, O. Filed Oct. 9, 1897.

613,794. Electric Railway. William M. Brown, Johnstown, Pa., assignor to the Johnson Company, Lorain, Ohio. Filed Jan. 22, 1898.

613,691. Life-Saving Apparatus for Street-Cars. Hosea W. Libbey, Boston, Mass. Filed Jan. 24, 1898.

613,719. Combined Car Brake and Fender. Harry J. Raisch, San Francisco, Cal., assignor to Barton Josephus Parker and George X. Wendling, same place. Filed April 13, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

613,838. Cap for Enclosed Arc-Lamps. Chas. E. Harthan, Lynn, Mass., assignor to the General Electric Company of New York. Filed April 23, 1898.

613,841. Phosphorescent Electric Lighting. Daniel M. Moore, Newark, N. J., assignor to the Moore Electrical Company, New York City. Filed Dec. 17, 1896.

613,918. Electric-Lighting System for Vehicles. Rufus N. Chamberlain and Albert S. Hubbard, Belleville, N. J. Filed Feb. 17, 1898.

613,955. Flash-Light Apparatus. Simon D. Alter and Lewis T. Young, Philadelphia, Pa. Filed March 12, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

613,669. Brush-Holder. Albert E. Doman, Elbridge, N. Y., assignor to the Elbridge Electrical Manufacturing Company, same place. Filed Feb. 4, 1898.

613,663. Connector. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Aug. 5, 1898.

613,648. Electric Switch. Fredrick A. La Roche, New York City. Filed Dec. 28, 1897.

613,692. Governor for Air-Compressors. Sam H. Libby and William B. Potter, Schenectady, N. Y., assignors to the General Electric Company of New York. Filed March 6, 1897.

613,735. Electric-Circuit Controller. Nikola Tesla, New York City. Filed April 19, 1898.

613,809. Method of and Apparatus for Controlling Mechanism of Moving Vessels or Vehicles. Nikola Tesla, New York City. Filed July 1, 1898.

613,851. Electric Regulator. William H. Chapman, Portland, Me., assignor to the Belknap Motor Company, same place. Filed March 21, 1898.

613,869. Controlling Device for Electric Motors. Frank J. Russell, New York City, assignor of one-half to Horace See, same place. Filed May 25, 1898.

613,840. Generating and Distributing Electric Energy. Charles M. Green, Cleveland, O., assignor to the General Electric Company of New York. Filed April 18, 1895.

613,881, 613,882. Generating and Distributing Electric Energy. Charles M. Green, Cleveland, O., assignor to the General Electric Company of New York. Filed Dec. 23, 1896.

613,894. Dynamo and Electric Motor for Driving Vehicles. John B. Sherrin, Ramsgate, England, assignor to the Britannia Motor Carriage Company, Limited, London, England. Filed Aug. 17, 1895.

614,025. Brush-Holder for Dynamo-Electric Machines. George L. Pratt, Atlanta, Ga. Filed June 2, 1898.

MISCELLANEOUS.

613,705. Electric Timing Race Apparatus. John I. McDonald, St. Joseph, Mo. Filed Jan. 4, 1897.

613,778. Indicator Signal. Parnell Rabbidge, Sydney, New South Wales. Filed Feb. 1, 1897.

613,877. Alarm. Charles A. Deal, Chicago, Ill. Filed July 29, 1897.

613,899. Instrument for Measuring Electric Currents. Earl C. Eldredge, Springfield, Mass. Filed June 20, 1898.

614,012. Primary Battery. Carl Koenig, Berlin, Germany. Filed Feb. 16, 1898.

DESIGN.

29,632. Cylinder-Cap for Arc-Lamps. Charles E. Harthan, Lynn, Mass., assignor to the General Electric Company of New York. Filed April 23, 1898.

TELEPHONE AND TELEGRAPH.

New Telephone Association.

The Kentucky Telephone Association was organized at Crab Orchard, Ky., on the 2d inst. with the following officers: President, A. H. Bastin, Crab Orchard; vice-presidents, J. S. Vanwinkle, Danville; E. T. Fish, Berea; and A. D. Shotwell, Somerset; secretary, James Maret, Mt. Vernon; treasurer, F. P. Cambest. The object of the association is the improvement and extension of the independent telephone service in Kentucky and for the mutual benefit and protection of its members. Nearly all Kentucky companies were represented at the meeting, and it is promised that a great improvement and many extensions will be had at an early date.

The Sioux City, Ia., *Times* says: "A contract has just been closed by the Home Telephone Company of Sioux City and the Independent Telephone Company of Des Moines, with Pierce, Waterbury & McAllister, of Mason City, for the construction of a metallic circuit line from Sioux City to Des Moines. Preliminary work on the line will be commenced at once and it is to be completed and in operation by September 1, 1899 The line, through the Des Moines exchange, will give Sioux City connection with the independent lines to the east and southeast and with the Haneman independent lines to the southwest as far as Topeka, Kan. It also will afford Des Moines and these east, southeast and southwest independent lines connection through the Sioux City exchange with northern Nebraska, the Dakotas and Minnesota. The proposed line will be independent of any lines now built or in process of building. It will be distinctly a Sioux City-Des Moines line.

Mutual Telephone interests were represented recently at a meeting in Des Moines, Ia. Among the lines represented at the meeting were the Mutual Company of Des Moines, by J. W. Hill; the Southwestern Telephone Company and Clearfield and Mt. Ayr Company, by D. M. Smith; the Perry Telephone Company, by G. M. Bandy; the Jefferson Telephone Company and the Boone-Marshalltown Company, by C. E. Wells, and the Central Telephone line by W. Brandt. Statements were made that before spring every town of any importance within 100 miles of Des Moines would be connected with that city. A line will also be run to St. Joseph. Oskaloosa and Ottumwa will be reached and also Ft. Dodge, Sioux City, Marshalltown, Boone and many other places. The companies in the Iowa Telephone Association now have lines reaching 184 towns. The Southwestern is talking of a line to Omaha and Council Bluffs.

The People's Mutual Telephone Company of San Francisco has filed a petition with the Supervisors requesting that it be granted a year's extension of time in which to comply with the condition of its franchise requiring that $100,000 must be expended during the first year thereof. The company explains that, owing to litigation, it has not been justified in proceeding with the work of constructing its system. It is represented that after a decision of the Supreme Court had been rendered in favor of the company, contracts were thereafter entered into for materials and supplies of an aggregate value of $176,500 and that preparations are now being made for the commencement of work that will cost $200,000. For these reasons it is submitted that the company is entitled to an extension of time.

The Kansas City (Mo.) *World* states that O. T. Spellman, an attorney, has asked Judge Slover of the Circuit Court for a writ of mandamus against the Missouri & Kansas Telephone Company to compel the company to furnish him the use of a telephone at one-half its present rate. The suit is brought under a section of the revised city ordinances of 1898 relating to telephones, which is similar to that decided illegal by Judge Wofford of the Criminal Court in 1895, with the provisions he held invalid left out. The present ordinance was enacted by the Kansas City council in 1897. It provides that telephones in the business district shall cost their users but $3 a month or $36 a year instead of twice that amount. Judge Slover has not yet passed upon the application.

A number of the most substantial business men and bankers in Wichita, Kan., are said to have perfected plans to incorporate a company for the purpose of building an entirely new telephone system in that city as a rival of the Missouri & Kansas Company. It is the intention of the company to place telephones in the business houses and offices at a price not to exceed $1 50 a month, and $1.25 a month in residences. A petition for a franchise has been drawn up to be presented to the city council at its next regular meeting.

The reasonable use of the streets of a city for the equipment of a telephone system, including poles and wires, is held, in Magee vs. Overshiner (Indiana) to be a lawful use, and not a new and additional servitude for which the abutting owner can claim compensation.

A Wireless Telephone.

The following item, which we find in an exchange, may give some suggestions to the gentlemen who are endeavoring to find some practical method of telegraphing without wires:

"A recent traveler among the Indians of Catuquinaru, in the Amazon region, between the rivers Embyria and Embyrasu, says they employ a wireless telephone. It is made by digging a hole in the ground inside the house and laying the bottom with coarse sand well piled. On this is laid a wooden drum, or hollow cylinder of wood, half-filled with fine sand and layers of broken wood, bone and powdered mica. The upper part of the cylinder, which is empty, rises above the floor of the hut, and is closed by leather, then wood and lastly india-rubber. Outside the cylinder is packed round with fragments of wood, leather and rosins, which is covered with hard rubber at the level of the soil. To use the apparatus the drum is struck by a wooden hammer, and the vibration is evidently transmitted through the soil. The answer is heard in the drum, which acts as a resonance chamber. Messages can thus be sent over 1,500 yards from house to house."

A meeting of the owners of three independent long-distance telephone lines of Southwestern Missouri and Southeastern Kansas was held at Fort Scott on the 2d inst. Action was taken toward a consolidation of the lines. This will make a system in strong competition with the Bell Telephone Company. The Union Telephone Company declared a 5 per cent. quarterly dividend and decided to extend its lines south from Moran and Iola to several county seat towns. At Girard it is proposed to connect with the line which encircles the mining towns of Missouri and Kansas.

The Hanamo Telephone Company is meeting with opposition in its endeavor to get a franchise to South St. Joseph. The Citizens' Company of St. Joseph is opposing it in the first place, and is opposing it strenuously. The reason is a matter of revenue entirely. The Hanamo is connected with up country points through the Citizens' central office in St. Joseph. It gets considerable stock-yards business. It demanded a lesser exchange rate from the Citizens' Company. This was refused. The outside company then decided to build its own line to South St. Joseph and applied for the franchise.

L'Illustration of Paris, remarking on the number of telephones in service in the United States, deplores the lack of readiness to employ these instruments in Europe. In Berlin, where there are 30,000 in use, the average number of calls is not more than seven a day—two in the morning and three or four in the afternoon. Among the European countries, Germany and England hold the lead, with 140,000 and 116,000 instruments, respectively. In France there are scarcely more than 35,000, while there are 62,000 in Sweden and 30,000 in Switzerland.

A despatch from New Haven, Conn., states that representatives of a syndicate have been canvassing Connecticut for the past few days with the idea of organizing telephone exchanges. The Southern New England Telephone Company is now in undisputed control of the situation. It is said that the new enterprise is sufficiently backed to offer a strong opposition to the old concern. Plans are on foot to establish telephone exchanges all over the State, and to apply to the next session of the General Assembly for articles of incorporation.

At Marietta, Ga., it has become a permanent business of the telephone company to serve subscribers with sermons transmitted over the wires. The Christian Endeavor Society of the Presbyterian Church in Marietta has had a telephone put in their church for the benefit of a member who has been confined to his room with rheumatism for ten years. It has proved a great source of comfort to him and his friends.

The Midland Telephone Company has completed its line connecting Adrian, Minn., with Ellsworth and St. Kilion. Arrangements are pending for a joint rate to be established with the Bell long-distance line, which will allow the local system's patrons to talk over the whole Bell system.

New Companies Incorporated.

The Green County Telephone Company, Greensburg, Ky. Capital stock, $3,500.

The Montpelier Telephone Company, Montpelier, O.—to maintain toll lines between villages in Williams and Fulton counties, Ohio. Capital stock, $15,000.

The Ohio Telephone Company, Columbus, O.—to operate a telephone system throughout the State of Ohio. Capital stock, $100,000. Directors: R. E. Jones, T. A. Simons, David C. Beggs, F. D. Simons, Howard Park, L. D. Myers and William C. Orr.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12⅝c.; Lake, 12¾@13c.; casting, 12½@12⅝c.

The Petersburg (Va.) Street Electric Railway was sold on the 10th inst. under foreclosure to its bondholders for $55,000.

The North Hudson Light & Power Company has filed a mortgage of $2,000,000 to the New Jersey Title Guarantee & Trust Company as trustee.

The trustees of the Street Railway & Illuminating Properties, Boston, have declared a distribution of $2 per share on the common stock, payable November 16. Books reopen November 16.

The United Traction Company of Pittsburg reports for the year ended June 30, 1898: Gross earnings, $1,469,907; operating expenses, $682,916; net earnings, $786,991; interest, rental, taxes, etc., $586,512; surplus, $200,479.

A meeting of the stockholders of the Southern Electric Light & Power Company of Philadelphia will be held in that city on the 23d inst. for the purpose of voting on the question of increasing the capital stock from $400,000 to $2,000,000.

The United Electric Securities Company, Boston, will receive proposals until 12 M. November 16 for the sale to the company of so many of its collateral trust 5 per cent. bonds of the fifth, sixth and ninth series as will be absorbed by $69,478.28.

At the annual meeting of the stockholders of the Manhattan Railway Company held in New York last week, no news regarding the projected equipment with trolley was given, and the meeting adjourned after re-electing the board of directors and receiving the annual report.

The directors of the Metropolitan Cable system of Kansas City, Mo., are contemplating an increase in its dividend rate from 2 to 4 per cent. Messrs. Ream and Armour of Chicago own about $700,000 of the stock, and Robert Fleming of Scotland about $800,000. Nearly $1,500,000 of the stock is owned by the Colling-Merriam interests.

There is a probability that something official will be announced this week in regard to the purchase of the Nassau road by the controlling interests of the Rapid Transit Company of Brooklyn. There have been many conflicting statements about the deal within the last three weeks, but we have it from good authority that no conclusive arrangement has yet been reached.

Bernard F. Gallagher has been elected president of the Edison Electric Illuminating Company of Brooklyn, N. Y., in place of Ethan Allen Doty, and Henry Siebert has been elected vice-president in place of Edward Packard. The new board of directors consists of Bernard F. Gallagher, Henry Siebert, J. H. Wallace, Daniel J. Creem, George A. Prince, A. W. Dater, Thomas E. Murray, William F. Sheehan, John G. Jenkins, Nicholas F. Brady, Horace C. Du Val, Royal C. Peabody and J. D. Fairchild.

A deed of trust was recorded at the office of the clerk of the Corporation Court at Lynchburg, Va., on the 7th inst., from the Lynchburg Electric Railway & Light Company, conveying to the State Trust Company of New York, trustees, its franchise and all its property for the purpose of securing the payment of $150,000 of bonds, which it is proposed to issue, the money to be applied to the furtherance of the plans of the company in the rehabilitation of their street railroad in Lynchburg.

By order of the board of directors of the Nashville Street Railroad of Nashville, Tenn., Vice-President Bradford gives notice that on the 31st of December the company will pay, on presentation at the First National Bank of Nashville, the principal and accrued interest of fifty bonds for $1,000 each of the South Nashville Street Railroad Company, being Nos. 1 to 50, inclusive, of Series A, secured by mortgage executed by said South Nashville Street Railroad Company. Interest on said bonds will cease after December 31.

The Kansas City (Mo.) "Star" states that the Standard Telephone Company has bought all the lines and equipment of the Central Missouri Telephone Company. This new purchase gives the Standard Company about 1,000 miles of line in Missouri, and when all connections are made it will give Kansas City communication with 150 towns. The Central Missouri system started at Versailles and ran north to Tipton, Booneville, Fayette and Moberly. From Moberly it ran to Mexico and Brunswick. It also connected Moberly with Macon, Gallatin and Trenton.

The Philadelphia "Stockholder" says: "Conspicuous among the 'mystery' stocks is General Electric. Signs are not wanting that a strong speculative clique will undertake to make it attractive marketwise. The current bull point is that net earnings for the past five weeks have been nearly $500,000. It is averred, furthermore, that the company is so burdened with orders as to be compelled to decline contracts calling for prompt delivery. The new stock is said to be in the hands of the pool originally identified with it, and it is declared that these interests will keep it well in hand and gradually advance it to par."

The latest report as to the promoters of the $25,000,000 company recently incorporated at Albany says that they are the Elkins-Widener syndicate of Philadelphia. It is now reported that the company (the New York Gas & Electric Light, Heat & Power Company) has bought for about $6,000,000 the Consolidated Telegraph & Electrical Subway Company of New York, as a necessary step in carrying out its alleged purpose of consolidating the electric lighting business of Greater New York into one concern, and using the surplus power of the street railroad systems in the general scheme for furnishing light and power. A New York writer for the Boston "News Bureau" says: "Some people who ought to be in a position to know what is going on say that among the possibilities is the furnishing of electric light and power by one great corporation for every electric plant in Greater New York, and that this power can be generated at a few central spots and distributed to the limits of the city as may be needed."

The "United States Investor" says: "Boston Elevated stock has been bought in the past week on its future possibilities—on what stockholders may get in the course of two or three years from now, after the elevated structure is completed and the stock has been advanced to $75 per share. As our readers know, only $50 per share has been paid in, the par value being $100, so that the quoted price, $75, means $150 for a full paid share. At present the company is paying on this stock dividends at the rate of 3 per cent. semi annually, or 6 per cent. per annum, which dividends come mostly from the surplus earnings of the West End Street Railway Company, after the charges of the latter company have been met. For a 6 per cent. stock $150 is a pretty good price, but it is figured by 1902 or 1903, say, the company will be earning 9 per cent. net on all the Boston Elevated stock ($10,000,000) after providing for all charges."

At the sale of the Brooklyn elevated roads at the New York Real Estate Exchange on the 10th inst. only three actual bids were made, and these were all by F. P. Olcott, chairman of the reorganization committee of security holders, to whom the properties were knocked down. The bids were as follows: Brooklyn Elevated, $1,750,000; Union Elevated, $3,075,000, and Seaside & Brooklyn Bridge Elevated, $682,500, or a total of $5,507,500. The sale was a foreclosure on the mortgages, and was the first step in the reorganization proceedings. The road has been in the hands of a receiver since November, 1896 and as soon as the new title has been perfected application will be made to the Supreme Court for the discharge of the receiver, when the road will be reorganized on a sound financial basis and with due regard to its earning capacity. President Uhlmann hopes to have the Fifth and Lexington avenue divisions of the system equipped with electricity by midwinter, and the whole of it will be thus equipped, it is expected, by 1900.

EDITORIAL NOTES.

Death of the Inventor of the Keely Motor.

The death in Philadelphia on the 18th inst. of Mr. John E. W. Keely closes the career of one who during the past quarter of a century succeeded in attracting more world-wide attention through the so-called Keely motor than almost any contemporaneous inventor. Some twenty five years ago the scientific world was startled by the announcement that a motor had been brought out which was to all intents self-operating, and to which Mr. Keely applied the name of "hydro-pneumatic-pulsating-vacuo engine." Scientists, engineers and capitalists carefully examined the motor and watched it operate, and enough confidence was felt in the future of the machine to induce several prominent New Yorkers to form a company capitalized at $100,000 with a view to perfecting the machine and placing it on the market. Machine after machine was built, all proving on being tried experimentally very erratic, sometimes operating and other times not. The principle of working this wonderful motor was kept secret, not even those most interested financially understanding its method of operation. In answer to all questions on the subject Mr. Keely invariably replied that the force made use of was "etheric vapor," but what that force was or how it was applied has never been divulged. By means of it however he proposed to revolutionize mechanics, and in 1875 is quoted as having made the following extravagant statement:

"I propose in about six months to run a train of thirty cars from Philadelphia to New York at the rate of a mile a minute with one small engine, and I will draw all the power out of as much water as you can hold in the palm of your hand. A bucket of water contains enough of this vapor to produce a power sufficient to move the world out of its course. An ordinary steamship can be run so fast with it that it would be split in two."

In spite of Mr. Keely's wonderful predictions, however, the motor never got beyond what might be termed the experimental stage. Exhibitions were occasionally given of its working in his laboratory before engineers and scientists, who endeavored in every possible way to solve the problem of its working, but without avail. Some of those who looked into the matter thought the propelling force was compressed air cleverly arranged to pass through minute tubes resembling in outward appearance wires, but as the motor was never allowed to be taken apart for inspection, these surmises could never be verified. It came generally to be believed however, after thousands of dollars had been spent by outside parties interested in an endeavor to perfect the motor for practical use, that the machine was a humbug so arranged as to operate by some one of the well-known forces of nature, and the fact that the motor was never put to practical use although backed by moneyed men would seem to bear out this belief. In any case the inventor of the Keely motor was undoubtedly an extremely clever man, and managed to derive, so it is alleged, a good living from the enterprise. If the carefully guarded secret of the operation of this machine was kept by the inventor to the last, little more will probably be heard of this Keely mystery, which has from time to time been exciting the curiosity of two continents during the past twenty-five years.

Automatic Stoking.

That automatic stokers are rapidly being adopted in large central stations is not to be doubted. This is especially so in lighting and power plants situated in the midst of thickly populated districts, owing to the necessity of providing some means of doing away with the smoke nuisance due to incomplete combustion of soft coal. A few years ago in manufacturing centers such as Pittsburg and St. Louis this incomplete combustion of fuel grew to be such a nuisance and brought forth so many complaints from the residents that the proper officials found it necessary to take up the matter if only for hygienic reasons. Committees were therefore appointed, and after a careful examination it was found that relief might be obtained and comparative cleanliness secured by the introduction of mechanical stokers. The cost of installing suitable mechanism for stoking purposes is comparatively high, although experience would seem to show that where automatic stoking has been resorted to the interest on the money invested for the purpose is more than made up for in the long run by the advantages derived, to say nothing of the abatement of the smoke nuisance, which of course as pertaining to the well-being of a community cannot well be reckoned in dollars and cents. The constant and uniform feeding of the fuel by an automatic stoker is conducive to thorough combustion, and where traveling grates are made use of a clean fire is assured. One of the results, and an important one from a pecuniary standpoint, directly due to this method of stoking would seem to be a greater evaporation of water per pound of coal than can be obtained by hand stoking. As an example, some tests made last month at the Belfast Electrical Works in Ireland showed the amount of water evaporated per pound of coal from and at 212° F. to be 11.59 pounds by the use of a mechanical stoker, whereas the hand-firing trial with the same coal showed an evaporation of water per

pound of coal from and at 212° F. of but 10.6 pounds. This would seem to indicate that a lighting or power station with a capacity of 6,000 horse-power hours a day would be obliged to consume, in order to obtain the same power, over a ton more coal a day were the stoking done by hand than if an automatic stoker were made use of. Another indirect source of economy resulting from mechanical firing is the greater length of life of boilers owing to the absence of sudden changes of temperature.

There are at the present day many different types of mechanical stokers on the market, all of which however resemble one another more or less in their operation. The principle on which they operate is quite simple. Hoppers or receptacles of some description are usually provided, into which the coal is deposited either by hand or by means of conveyors. The coal is then pushed forward by either a continuous or intermittent movement on to the grate bars in the furnace. In some types of automatic stokers these grate bars have a reciprocating motion, in others they are made in the form of an endless chain, but invariably they are so arranged that the coal travels toward the back of the furnace. Of course one of the main objects to be attained is the spreading of the coal evenly over the grate bars, and this is accomplished by various devices. In some cases where complete combustion is desirable, as for instance where a power station is located in the heart of a city, a combustion chamber is located at the back of the furnace through which all the gases are obliged to pass before escaping to the open air.

The fact that automatic stokers are conducive to a saving in fuel probably accounts for their gradual adoption by large lighting and power stations, and for this reason rather than with any idea of abolishing the smoke nuisance, mechanical firing will undoubtedly become more and more popular, especially now that the mechanism for this purpose is rapidly being brought to a high state of perfection.

The Lighting of the Capitol at Washington.

The recent explosion in the Capitol at Washington, resulting in $20,000 damage and the loss of many valuable documents, now attributed to leaking gas, will it is thought have a tendency to hurry the necessary steps looking to the introduction of electricity throughout the building, thus completing the installation of electric lighting which was begun a year or two ago. In cases of violent explosion such as that referred to above, it very frequently happens that electric lights in the vicinity are extinguished owing to a rupture of the conductors or to a breaking of the lamps by the shock. An examination, however, made immediately after the explosion and fire, showed that the electrical installation in the Capitol had in nowise suffered, the incandescent lamps in the basement continuing to burn during and after the explosion, or until it was thought advisable to cut out of circuit the old portion of the building where the explosion took place, so as to avoid any possibility of the live wires interfering with the work of the firemen. Tests were made to ascertain if the circuits were in order, and at no time were there indications of grounding. This may be partially accounted for in the fact that the wiring of the building was done in a most thorough and efficient manner. It was thought at one time that the explosion might have been due to the eating away of a gas pipe by some stray lighting current, but this was shown to be impossible owing to the nature of the wiring. The conductors are all heavily insulated, carried in brackets supported on porcelain knobs, and nowhere make direct contact with any metal.

During the past two years many changes and improvements have been introduced in the Capitol, but probably none have attracted more attention than the electrical equipment in its varied branches. First and foremost among the improvements, at least so far as the comfort of the public is concerned, was the placing of electric lights all through the grounds during the spring of 1897. The past summer has further seen the installation of electric lights in the old Senate Chamber, which is now the home of the Supreme Court. At the present time the work of installing an electric elevator in the Senate end of the building is rapidly progressing and is expected to be completed before the opening of Congress. Preparations have also nearly been completed for the installation of a 250 HP. generating set with a capacity of 3,000 additional lights, or in other words a duplicate of the one installed a few months ago on the Senate side. As soon as the extra plant is completed it is proposed to adopt electricity for almost every purpose, such as the running of elevators, ventilating fans, etc. Gas is still used to a small extent in the Senate end of the building, in a portion of the old building, and for lighting the dome, but taking into consideration the large amount of damage recently occasioned by this form of illuminant, the sooner it is abolished from the Capitol and electricity adopted the better it will be for the safety of the noble pile and all it contains.

Under the Searchlight.

Notes and Comments on Various Topics.

Two clerks in a New York uptown grocery store are firm believers in the force, fierceness and mysterious ways of electricity, and furthermore are now prepared to believe right away anything that Nikola Tesla may claim to be able to do with the electric fluid. These two young men put in a bad quarter of an hour a day or two ago dodging a live wire in action at close quarters, and though they have escaped with nothing worse than unstrung nerves and sundry bumps and bruises from coming in contact with brick walls, they don't want any more such experiences. Time was when the keeper of the grocery used electric light in the store, but he dispensed with it on the ground of economy. It was cut off save in the cellar, where the wires were encased in an iron pipe. On the day in question the two young men were back in the cellar arranging the stock, when what they described as a streak of blue flame burst from the wires in the iron piping, and continued spitting and sputtering in a continuous stream clear across the cellar and barring their exit by the only doorway. After standing the pyrotechnics for about ten minutes and noticing that the wall opposite was getting blackened, one of them thought it time to go for assistance. He placed an empty cracker box over his head and started, but weakened and gave up the job. Then the pair set up a Macedonian cry, and the brother of the proprietor started down the cellar steps. He took in the situation at a glance and then backed up stairs again. His first thought was the telephone, but not knowing what shape that might be in he abandoned it and turned in a fire alarm. An engine company responded, and the assistant foreman running down into the cellar, seized a bale stick, and with a blow on the exposed wire from the iron tubing evidently broke the connection, for the fiery display ceased. Nobody offered any scientific explanation of the occurrence, but all agreed that the fireman had done a risky thing in attacking a live wire with a club.

* * *

True to their custom and their humor on holiday occasions, the American Electrical Works of Providence, R. I., Eugene Phillips general manager, have issued for distribution a Thanksgiving souvenir which is in line with the many amusing conceptions the company have sent forth to add to the felicities of the days they wished to commemorate. The present souvenir consists of a folding card having three parts, on one of which is the picture of a fine plump turkey in a baking-ban, apparently either ready for the oven or for the table, and of a most appetizing appearance. Beneath this, fastened on the card, is what might be taken for a pencil case, but turns out, when examined, to be a small wooden tube, which contains an explanation of the inscription printed beneath, "The point is within." To get at the "point" you pull a stopper to which is attached a large needle with a coil of thread around it, at once suggesting the use to which it might be put in preparing a turkey for the oven. The point of course is on the needle. On the other folding part of the card is an engraving exhibiting all the familiar table attractions of the Thanksgiving dinner, and in the midst, looking quite captivating, "the little brown jug." The middle section of the card is devoted to an explanation of the illustrations and of the courteous intent of the popular company as follows:

Thanksgiving, 1898.

Thanksgiving Day is approaching. We want to remember our friends, so we send you herewith some of the indispensables of a well regulated Thanksgiving dinner—a Rhode Island turkey and "fixings" and a mince pie from a recipe long held in veneration in our family, "Aunt Sarah Ann's Thanksgiving rule," which contained an extra amount of Plums.

Of course we couldn't send you a *real* mince pie or a *real* turkey but we do send a *real* basting needle all threaded for sewing up the turkey. (See the point?)

Our best wishes for an enjoyable day.

By the way there's another point we want to mention—Wire, both Bare and Insulated. You know who makes the best; no need for us to say more.

American Electrical Works,
Providence, R. I.

Dr. William P. Sensibaugh, a dentist, of Port Byron, Ill., is in a serious condition as a result of a prank played upon him while being initiated in a fraternal insurance lodge. Several slight shocks from a live wire were given to him while he was blindfolded. One of the initiating officers, seeing the candidate was about to evade the wire, gave him a little shove, which threw the dentist off his balance, and he fell hands down upon the battery itself, receiving a shock which made him unconscious. After working over him for two hours and finally reviving him it was discovered that his right arm hung limp and loose, and in this condition it has remained ever since. Soon after, Sensibaugh was stricken with an affection of the pneumogastric nerve, and he has been kept up mainly through electrical treatment. One of the attending physicians says that paralysis of the nerve is threatened, in which event the sufferer cannot live.

* * *

The French are nothing if not original. Since the question as to whether decapitation causes instant death or not, the French Government is said to be seriously considering the adoption of an electrically operated death helmet in lieu of the guillotine. The machine somewhat resembles in appearance the headgear worn by the knights of old. From the top curves a long hollow bar of steel, dividing near its end into two portions, each of the latter terminating in the proximity of two openings in the helmet. In these bars are located two movable appendages to the extremities of which are fastened two long curved needles. In operation these needles would be thrust forward by means of an electric current passing through the mechanism and would bury themselves in the eyes of the criminal, causing instant death. Though possibly an improvement over the guillotine, we doubt if this method of execution would prove popular with the masses in France, who apparently revel in riot and bloodshed.

ELECTRIC CONDUIT SYSTEMS.

BY W. L. HEDENBERG.

When electric traction was first thought of, about twenty years ago, many of those interested in solving the problem went about it in what appeared to be the simplest way, by placing a conductor either along the surface of the ground or just below it. Notwithstanding the fact that the current supplied was at low voltage, the attempts were in the majority of cases failures both from an engineering and financial standpoint. Shortly after these unsuccessful attempts at underground traction, an overhead system of electric traction was developed and successfully tried in Kansas City which for the time being drew attention away from conduit systems. Hundreds of miles of overhead trolley lines were then built in various parts of the country and successfully operated, while the conduit systems had not yet gotten beyond the experimental stage. Although economical to construct and fairly economical to operate, defects in the overhead system became more and more apparent, especially for urban use, and inventors again turned their attention to conduit

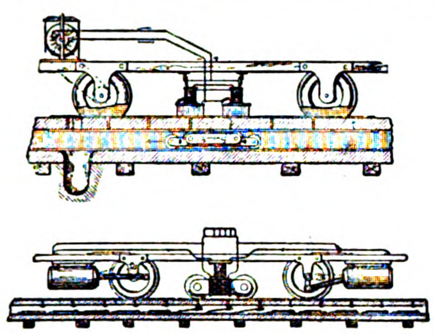

FIG. 1.
Van Depoele Closed Conduit Systems.

traction. During 1887-1888 a number of conduit systems were brought out. Some of these were tried experimentally on short stretches of track with questionable success. The aim of these early inventors was apparently to develop a conduit system which could be built for from $12,000 to $15,000 a mile, and thus successfully compete in cost of construction with the overhead trolley. This necessitated the laying of a very shallow conduit, with the result that the latter was constantly getting out of alignment with the track and causing the plow on the car to frequently run off the conductor. Another defect to be overcome was loss of current through leakage, which invariably occurred in wet weather. In the early nineties the conduit systems which were being experimented with in this country could be divided into three general classes—those having a sealed conduit, those having a semi-open or slotted conduit and those having an open conduit. The object of a sealed conduit was to prevent moisture as far as possible from reaching the conductor, with a view to reducing the loss of current through leakage. The conduit was usually located in the center of the track and provided with an exposed rail or contact pins for collecting the current. The surface conductor was almost invariably thrown in circuit through the medium of a powerful magnet carried by the car and acting on some switching mechanism in the conduit. Two systems of this description are shown in Fig. 1, both invented by Van Depoele. In the upper illustration a magnet on the car draws along a contact carriage which establishes electrical connections between the conductor in the closed conduit and the surface plate through the medium of contact pins. The current is then collected by metal brushes and delivered to the motors. The lower cut shows another form of surface contact system in which electrical communication is established between the conductor in the sealed conduit and the surface plate by means of movable arms which are lifted by the magnet on the car. An early contact system very similar to that just described is shown in Fig. 2. This system, invented by Pollak and Binswanger in England in 1886, apparently differs from that of Van Depoele only in the arrangement of the magnets and in the means used for collecting the current. In another type of closed conduit a movable flat conductor is made use of, which is raised from the bottom to the top of the conduit as

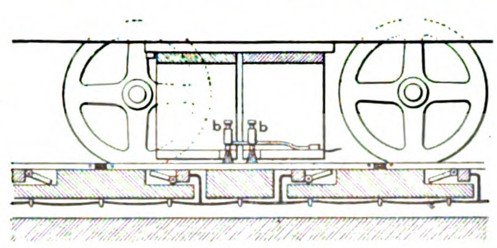

FIG. 2.
Pollak and Binswanger Closed Conduit System.

the car passes over it, as usual through the medium of an electro-magnet. In all systems of this description the surface plate is invariably divided up into short sections of from six to fourteen feet in length, insulated one from the other. By this arrangement there is no live section except that directly under the car.

Patents have been granted on numerous closed conduit systems, none of which, however, have gotten beyond the experimental stage. The objections raised against this type of conduit are that in winter it would be difficult to keep the surface contact plate free of snow and ice, and that where there are movable parts in a conduit which cannot readily be gotten at there is always danger of, for instance,

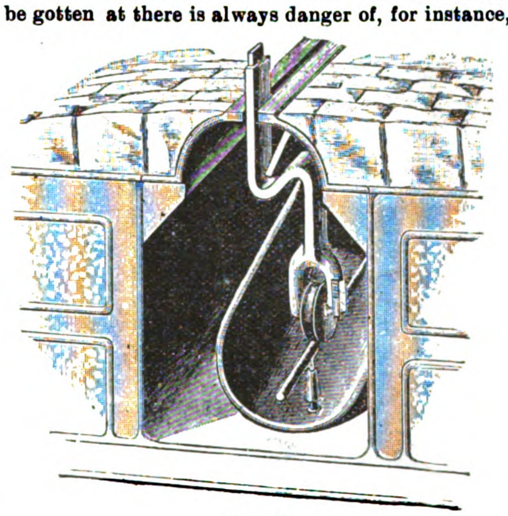

FIG. 3.
Griffin Semi-Closed Conduit System.

an arm not dropping after a car has passed, thus leaving the surface contact alive. In short, the sealed conduit has not proven successful if we except possibly an experimental line now in operation in England for which great things are hoped.

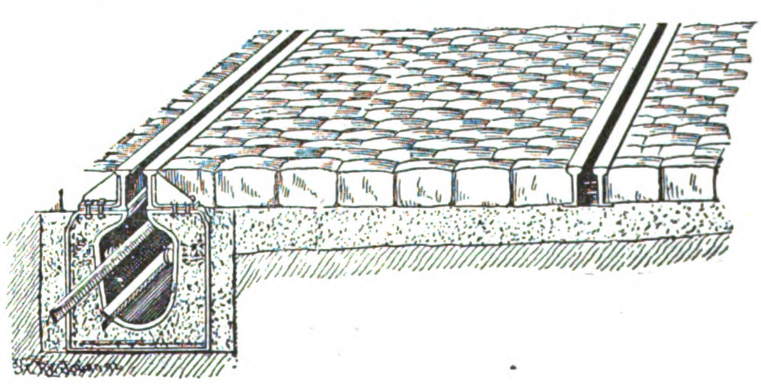

FIG. 5.
Section of Budapest Conduit Electric Railway.

Of the semi-open type of conduit there are innumerable examples. The idea of those who have invented this style of conduit was as a rule to gain all the advantages to be derived from the use of a direct movable contact and at the same time shield the conductors from dampness with a view to preventing loss of current. An example of this type of conduit may be seen in Fig. 3. Here, as will readily be seen, the plow bends into a second compartment arranged so as not to collect water. Almost every conceivable combination of mechanism has been thought of in this connection and scores of patents granted.

Another type of semi-closed conduit is shown in Fig. 4. In this system the conduit, which is but 12 inches deep, is placed under one of the track rails, the plow having two small grooved wheels as well as a sweeper attached to it, fastened to the side bars of the truck. As the plow moves forward it lifts a short rod which, as may be seen by the illustration, throws a switch allowing current to pass from the main feeder to the rod from which it is collected and delivered to the motors. As in most all systems of this type, but one section of rod is charged with

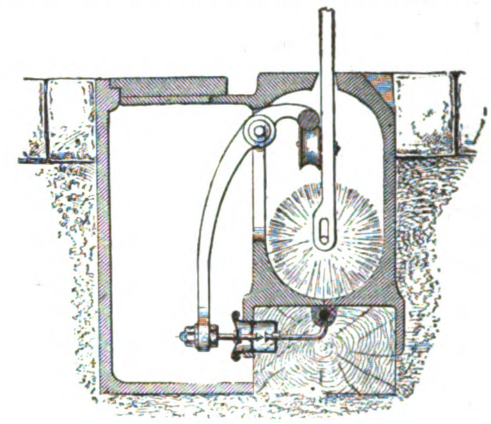

FIG. 4.
La Burt Semi-Closed Conduit System.

current at a time and that section is directly under the car. The cost of such a conduit system is given by the inventor at from $10,000 to $15,000 a mile, according to the conditions and requirements. A few of these semi-open systems have been tried on an experimental scale, but with scarcely more success than with the sealed type of conduit. In the majority of cases the difficulty lay in the complexity of the mechanism and in the endeavor of the inventor to keep the cost per mile down to from $15,000 to $20,000. In other words, most of the designs brought out were for cheap systems and consequently gave poor results even when tried experimentally.

Under this head of semi-open conduits it might be in place to mention a rather novel railway system invented about a year ago by a resident of Chicago. The conduit is quite shallow, being but sixteen inches in depth by four inches in width. In the pavement on either side of the slot are located two castings. Through the center of the latter a large circular hole is bored at right angles to the line of the track. Within this aperture a movable brass cylinder is located and within the cylinder is placed a heavily insulated metal rod. On the end of the

latter, which extends into the conduit, is an ordinary trolley wheel. The movable brass cylinder is provided with two springs which tend to move it forward and away from the charged conductor. Each car is equipped with a wedge-shaped plow, twenty-one feet in length, which, when the vehicle is in motion, strikes between two opposite pulleys, one positive and the other negative, and presses them back against the action of the springs. In this manner connection is made with the line conductors situated under each rail. The current then passes through the insulated metal rod and by means of the trolley

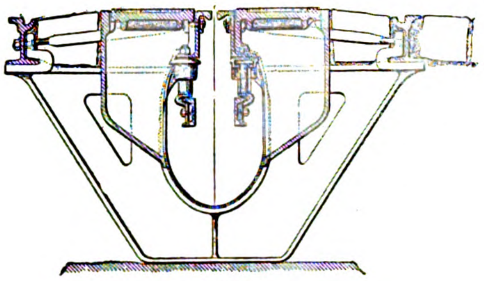

FIG. 6.
Yoke used on Lenox Avenue System.

wheel to the plow on the car and from there to the motors, the negative current passing out in the same manner on the opposite side. As a plow on a car is slightly longer than the distance between the switch boxes, the front of the plow reaches the next set of pulleys before it leaves the rear set, thus insuring a continuous flow of current through the motors. The general arrangement in this system, as will be observed, is the reverse of that usually met with, the long plow on the car in reality taking the place of the continuous conductor. The inventor claims that this system is a great improvement over the designs heretofore brought out, there being no current in the conduit except where the car happens to be, and the end of the rod where it is pushed in to receive the current being in an air-tight space where no water or moisture can gain access. An attempt was made some time ago to induce a Chicago street railway company to give this system a trial, but whether this has been done or not the writer is unable to say.

In the summer of 1889 a conduit system with a bare conductor was for the first time successfully operated in Budapest, Austria-Hungary, and attracted wide attention. The conduit was located, as shown in Fig. 5, under one track rail. It is oval in shape, 11 inches wide by 16 inches deep, lined with iron embedded in concrete and supported every four feet by iron yokes. The slot, which is over an inch in width, is made up of two beam rails having no inside lower flange and fastened to the conduit by angle irons. The conductors, both positive and negative, are made of angle iron secured by means of suitable insulating material to the casting. They are sufficiently high above the floor of the conduit to be protected from any water which may find its way in. The current is collected by means of a double tread wheel with a flange in the center. The success in the operation of this road was apparently due to a combination of circumstances. In the first place, no expense was spared in the laying of the conduit to ensure its solidity and durability. As previously stated, iron yokes were used throughout with a view to keeping the conduit in perfect alignment. Another circumstance which tended to the successful operation of this system was the climate, there being comparatively little rainfall.

A careful study of the Budapest electric conduit system convinced many of those engaged in solving the problem of conduit traction that a system in order to work successfully would have to be built in a substantial manner and less pains taken in shielding the conductor than in properly draining the conduit and having it sufficiently roomy to allow of the conductor and its supports being frequently inspected. Accordingly in 1894 the Metropolitan Street Railway Company of New York City began the construction of an electric conduit system on Lenox avenue. With a view to converting this road into a cable line providing the attempt at electrical traction proved a failure, the conduit was built in a most substantial manner. Heavy iron yokes were placed at intervals of five feet to support the conduit and the latter was embedded in concrete. As shown in Fig. 6, the electrical conductors were suspended by suitable insulators every fifteen feet, at which points

FIG. 7.
Underground Trolley Construction on Fourth Avenue.

hand holes were built to allow of frequent and careful inspection. This line was completed in June, 1895, and was given a thorough trial during the winter of 1895–96. With a view to reducing to a minimum the chance of an accident occurring, at first a voltage of 350 was used, which however was

FIG. 8.
Some of the difficulties encountered at Fourth Avenue and Fourteenth Street.

found not to be economical and was subsequently raised to 500. With the exception of a few unavoidable mishaps the line worked satisfactorily, neither snow nor rain causing it to fail through excessive leakage.

The Lenox avenue line having proven successful, the same system with a few changes was then rapidly installed on the Second avenue, Madison avenue, Eighth avenue, Amsterdam avenue and Fifty-ninth street lines. At the present time steps are being taken towards abandoning the cable on Broadway for electricity, while an electric conduit system is being substituted for the out-of-date horse cars on the Sixth avenue line. It is the intention of the Metropolitan Street Railway Company to gradually do away with cable traction on all of its lines, substituting for it conduit electric traction, as the latter motive power has been found more flexible for crowded thoroughfares as well as more economical in operation. In a recent article published in the *Street Railway Journal* giving the operating expenses of the Metropolitan Street Railway Company during the past year, the cost of the various methods of traction are given as follows: Horse lines 17.87 cents per car mile, cable lines 16.42 cents per car mile, and electric traction 10 23 cents per car mile. The converting of a horse car line, as for instance that on Sixth avenue, to electricity is exceedingly costly, owing to the depth at which it is necessary to excavate and the large number of underground structures, such as water and gas mains, which it is necessary to lower or move to one side. An idea of the

amount of work the building of an electric conduit system entails in New York City may be gathered from Figs. 7 and 8. The actual cost per mile of single track usually ranges between $60,000 and $80,000, depending of course on the number of obstacles encountered. With a view to being in a position to generate sufficient power to operate all its electric lines in this city when completed, the Metropolitan Street Railway Company is at present erecting a mammoth power house at Ninety-sixth street and First avenue. The building when finished will occupy a space of about 55,800 square feet and will rest on an extremely solid foundation, consisting of some 8,000 piles covered with a four foot layer of concrete. A view of the station in course of construction is shown in Fig. 9. The completed station will have a capacity of 70,000 horse power. The engines of 4,000 nominal horse power each will be located in a room 200 ft. in length by 110 ft. in width. The boiler room will contain 87 water tube boilers rated at 250 HP., with a maximum capacity however of 400 HP. each. The generators will be of the three-phase alternating-current type capable of transmitting current at a pressure of 6,000 volts. To ensure a good draught the chimney will be 350 feet in height with a diameter of 22 feet.

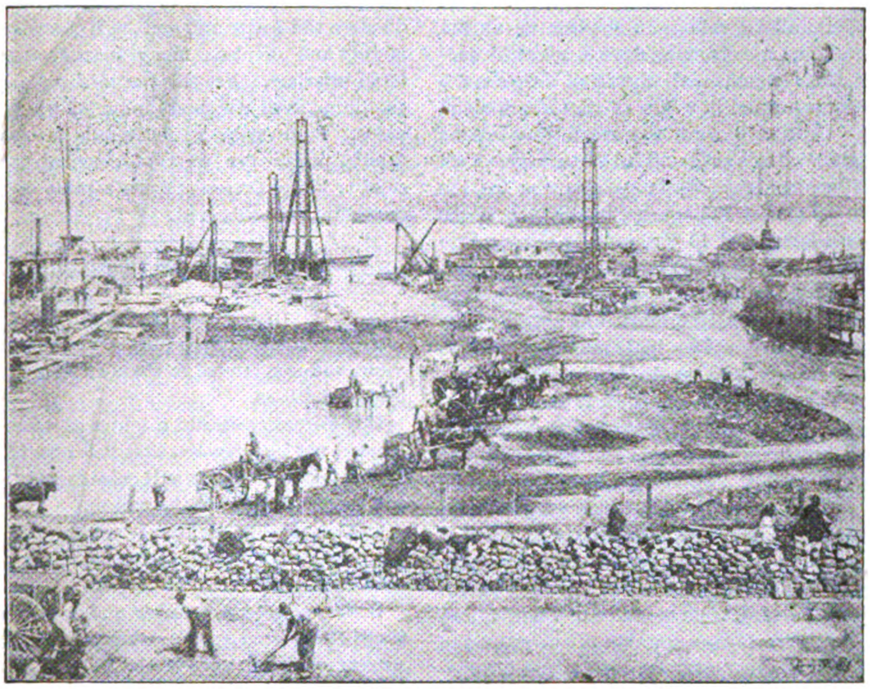

FIG. 9.
View of Power House Site, Ninety-sixth Street and First Avenue.

At the present time, out of about two hundred miles of track controlled by the Metropolitan Company in New York City, some seventy miles are operated by electricity, and the latter motive power is being so rapidly substituted for other forms that the dawning of the new century should find but few if any cable or horse lines within the city limits, especially now that the Third Avenue Railroad Company has also recently decided to operate its lines electrically.

Constitution and Resistance of Mercury.

At the recent congress held by La Société Allemande d'Electrochimie at Leipzig, a paper was communicated by M. Liebenow with regard to the constitution of mercury. From his experiments it appears that the electrical resistance of the alloys depends principally upon the molecular grouping, i. e., upon the number of atoms forming the molecule of the solid substance. In the case of solid mercury the molecular grouping is extremely complex, but in the gaseous condition it is probably monoatomic. It is remarkable that, whereas for most pure metals, including solid mercury, the temperature coefficient for resistance is in the neighborhood of 0.004 per 1° C., whilst for liquid mercury the coefficient is only 0.001. Liquid mercury appears to be a mixture of monoatomic molecules and the more complex groupings characteristic of the solid condition.

IMPROVEMENTS IN THE ARC LAMP.*

BY ROBERT A. ROSS, E. E.

The prominent place which the arc lamp took in the earlier years of electric lighting, involving as it did the designing and operation of the complicated series arc machine, has always excited comment, and the permanency of the types of apparatus then designed is astonishing. From the commercial beginning of arc lighting in the year 1879 up till the present, the direct current series lamp has undergone comparatively little change except in the smaller details. It is true that during the earlier years the questions of open and closed circuit types, of clockwork, clutch and rack feeds were fiercely discussed, but the lamps which have stood the test of time and which are now considered good commercial articles are much as they were when originally designed.

During the first eleven years of its existence the series arc lamp stood alone, in spite of the fact that the need was apparent for other types which would operate on the constant potential lines of direct and alternating systems. The result of the attempts to develop these types has been to produce in 1890 the constant potential direct current arc lamp to operate two in series on the 110 volt incandescent service lines, to give us, about 1892, the alternating current constant potential type, and in 1894 the enclosed type of the direct current arc.

At the present time all of these types are in successful operation, and in addition during the past year the enclosed alternating lamp has attained a thoroughly commercial form. The development of the several arc lighting systems by series, parallel, direct and alternating current distribution has depended upon the development of suitable lamps alone, and gave us the series direct current system first, because of the simplicity of operation of the series lamp. The reason of this simplicity of operation is not far to seek, if we remember that after the arc is struck the regulating mechanism performs but one function, namely, to regulate the arc voltage, the current regulation being done at the machine regulator. On the other hand, the lamp mechanism for operation between constant potential lines regulates the arc voltage as well as the current, and as a consequence there is going on at all times a struggle between the forces by which these two factors are governed. It is this chiefly which necessitates the placing of a resistance in series with these lamps to prevent pumping. This trouble is not so apparent in the alternating type with which a choke or economy coil is used, as in addition to the resistance of the coil the inductance is of effect to dam back excessive current rushes. Another feature which long held the lamp for parallel operation in the background was the fact that the art of carbon-making had not advanced sufficiently to admit of the commercial manufacture of the high grades necessary for its successful operation. On the other hand, the force which has been of greatest effect in developing the constant potential type was the necessity which existed for the use of arc lamps on the incandescent service lines and the consequent uniformity and simplicity of the line and station equipment. The advantages attendant upon the use of the constant potential lamp have at the present practically banished the series arc from the field of interior lighting, and in many new plants are leaving no place for it even in what has been considered its own peculiar field, that of street lighting.

The question whether the series arc will retain its supremacy for outside illumination will depend largely upon whether machines capable of being direct connected or at least belted direct to fair sized engines can be built and operated. There seems to be a fair prospect of this, if we are to judge by the results of the past four or five years, within which time the limit of size has passed from about sixty to three times that number of lamps per machine. It is evident, however, that the limitations of safety will prevent the grouping of any such large number as might be desirable for other reasons on a simple series loop, and will force the adoption of systems of return loops as in the Brush machine, where several circuits are run from the same machine and the line to line potential on each circuit correspondingly reduced, or by some other series parallel grouping of circuits which will give the effect of keeping down excessive line voltages while admitting of the use of large units in the station.

The advantages which the series system possesses for the distribution and control of light over large areas when coupled with the equally evident advantage of the use of alternating current generators, which are the standard type for most stations, have long been recognized, and some fairly successful attempts have been made to use alternating current lamps on series alternating circuits taken either from the constant potential bus bars of the station which feed the incandescent service primaries, or from the same bus bars through a self-regulating transformer, which gives a constant current through the lamps placed in series on the circuit. As to the operation of these circuits there appears to be no great difficulty, and were it not for the fact that the light distribution from the alternating lamp is poor, and the cost of the superior carbons, which are necessarily so high, there is no apparent reason why this system should not displace the direct current series system with its separate and special generating units, thus permitting the distribution of incandescent and arc lighting from the same generators and the separate control of the arc lights as on the direct current series system at present in use. There appears to be a large field for this system in spite of the disadvantages mentioned above.

The development of the enclosed arc lamp has been a curious example of the effect of preconceived ideas in holding back much needed inventions. As early as 1846, Staite recognizing the need for the enclosed arc with its long burning advantages, undertook its development, but without success, as were

* From *Canadian Electrical News.*

the efforts of others up till about 1894, when the lamp became a commercial success. The chief reason for the failures up to that time was that the endeavor had been to produce an arc similar to that in the open series lamp, which in the light of later knowledge was a mistake.

The open lamp has a normal arc of 45 volts, while the enclosed works to best advantage at about 80, the arc at the higher potential being much more stable and giving a better distribution of the light than at the lower voltage at which most of the experiments up till 1894 had been made. In addition to this misconception of the value of the long arc which enclosure made possible, the difficulty of obtaining enclosing globes which would withstand the heat, and the commercial impossibility of obtaining pure carbons which would not darken the globe, delayed seriously the appearance of the enclosed arc. These difficulties overcome, the increased voltage of the arc which in the series system is a disadvantage, were seen to be of decided advantage, as it enabled the lamp to be operated and controlled singly from the constant potential 110 volt lines from which the incandescent lighting was wired instead of two in series across the lines as the practice was with the open arc.

In comparing the relative advantages of open and enclosed arc lamps we find as follows:

1. That the enclosed type will burn for from 100 to 150 hours with one recarboning, as compared with 8 hours for single open lamps, the cost of the carboning and trimming being reduced in proportion.

2. For operation on constant potential circuits the ability to operate one enclosed as compared with two open lamps across the mains is a very evident advantage.

3. No dust, sparks or hissing from the enclosed lamp.

4. Simpler mechanism, and better regulation due to the longer arc, and less flickering in the enclosed type, as it feeds but one-fifteenth to one-twentieth as often as the open arc.

5. As compared with the series circuit open arc, the enclosed constant potential lamp operates on a low and very safe voltage, and may be handled and operated precisely as an incandescent lamp, thus making it especially suitable for interior illumination.

These are all advantages on the side of the enclosed type, but against this we must balance the decreased light giving power per watt of consumption due to the use of the opaline or ground enclosing globes which are necessary for the proper diffusion of the light, and the loss of light due to the smutting of the globes with carbon dust, which becomes a serious matter after about 100 hours of running; also there is the extra cleaning of the enclosing globe and the maintenance of same.

For interior illumination, however, where a ground globe is a necessity for proper diffusion in both cases the open and closed types are on an equality so far as light giving efficiency is concerned.

It appears, therefore, that for all purposes of interior illumination and in many cases of outside lighting, the enclosed arc has decidedly the advantage, and the records in the larger cities of the United States show that these advantages have been recognized, and for most of the new installations of arc lamps the enclosed has been selected as the most suitable.

For the purpose of showing the different light giving efficiencies of the various types of lamps, as well as to place in accessible form the usual voltages and amperes in use in their respective arcs, the following table has been figured on the basis of 450 watts consumption at the arc in each case, that being the standard usually adopted. To complete the combinations all of the probable systems are considered, although several are not much used as yet, but the figures indicate what may be expected when they are adopted as the lamps are developed for all of them:

LIGHT-GIVING EFFICIENCIES OF DIFFERENT ARC LIGHT SYSTEMS.

	Amperes.	Volts in		Watts in		Candle power.		Watts. Per C. P.		C. P. per H. P.	
		Arc.	Line.	Arc.	Line.	Outside.	Inside.	Outside.	Inside.	Outside.	Inside.
	1	2	3	4	5	6	7	8	9	10	11
Direct Current.											
Serie open	10	45	50	450	500	650	450	.7	1.0	750	520
Series enclosed	6.5	70	75	450	500	875	450	1.2	1.0	440	520
Constant potential open	10	45	55	450	550	650	450	.7	1.0	750	520
Constant potential enclosed	5.6	80	104	450	580	875	450	1.2	1.0	440	520
Alternating Current.											
Series open	15	30	33	450	500	375	300	1.2	1.5	470	370
Series enclosed	6.5	70	75	450	500	225	300	2.0	1.5	285	370
Constant potential open	15	30	33	450	500	375	300	1.2	1.5	470	370
Constant potential enclosed	6.5	70	75	450	500	225	300	2.0	1.5	285	370

Columns 1 and 2 give the volts and amperes at the arc; column 3 the voltage in the line or at the terminals of the transforming device, which is necessary for their commercial operation. Column 5 gives the consumption in watts at the terminals of the lamp. Column 6 gives the mean illumination of horizontal surfaces or the useful illumination from the lower hemisphere of the lamp, allowing for the absorption of light of 10 per cent. in the clear globe of the open lamp, and 40 per cent. in the opaline globes which are necessary for the enclosed type. If opaline or ground globes be used for all types, as should be done in the illumination of interiors, the useful candle power is given in column 7, in which due allowance has been made for the effect of the upper hemisphere of light, of which it has been considered that 50 per cent. of that passing above the horizontal lines is reflected from walls and ceilings and becomes useful. These figures have been obtained from a number of tests which vary widely, and can be considered as being as nearly as possible an approximation to average conditions. Columns 8 and 9 give the average watts at the arc per useful candle power figured from columns 6, 7 and 4, and indicate the probable consumption of energy in the arc per useful candle power for inside, and for outside lighting with the several systems. Columns 10 and 11 are figured from columns 8 and 9 and indicate the useful candle powers which may be expected per belt horse power in the station, allowing for fair average commercial efficiencies of generators, lines, transformers, choke coils, etc. The figures in column 10 indicate that for out-door illumination, where clear globes are used on the open lamps and opaline on the enclosed type, to give a proper distribution the useful light giving efficiency of the direct current enclosed type is 60 per cent., of the alternating current open type 70 per cent., and of the alternating current enclosed type 40 per cent. of the direct current series arc per unit of energy in the station at the dynamo pulley. Column 11 indicates that for interior illumination where opaline globes are used on all types to get proper dispersion, the direct current lamps on all systems are on a par, and the alternating lamp efficiency in all cases about 70 per cent of the direct. In considering these results it must be remembered that the series machine is much less efficient than the constant potential machine, which makes up for the smaller efficiency of the lamps on that system, and that the alternating arcs have a large light giving area above the horizontal which is considered as partially useful in columns 7 and 11 for inside lighting, but is considered as wasted for out-door illumination in columns 6 and 10. The direct current type, owing to the shape of the positive carbon, throws its light mainly downwards, and the upper hemisphere of light plays little part in interior illumination.

From the above considerations it appears that for outside illumination the series open arc will hold its own where the question of the simplification of the plant by doing away with the arc machines is not given first place. For interior lighting on the other hand, the enclosed direct current, or the alternating lamp of either open or closed types, will certainly displace the series arc, and will broaden that field largely and displace many incandescent lamps in large interiors. For this purpose arc lamps of small candle powers which are now offering will find a place. It must be remembered however, that the candle power per watt of consumption for these smaller lamps decreases quite rapidly as the current consumption is lowered.

HOW FUEL IS WASTED IN CENTRAL STATIONS.

BY F. BRUTON.

This article is from a purely mechanical point of view, and is intended to show how fuel is wasted in central stations.

However insignificant a source of waste may seem, it must not be forgotten that it is one of the many, which taken together will considerably increase the coal bill at the end of the month.

Taking the boilers first, it may be said that one of the greatest sources of waste is the leakage from the safety valves.

If the boilers are working under favorable conditions, there is no excuse whatever for the slightest wheeze of steam, and where the valves are allowed to blow continually at full steam pressure, or 5 lbs. under, it shows gross neglect.

It is a great mistake for boilers to blow off at or about the working pressure. The safety valve should be regulated so as to lift at 5 lbs. above the working pressure. This will give the fireman a chance to "burn down" and "clean" his fires without letting the steam down below the working pressure, and avoid blowing off.

Nothing is more distracting and confusing than steam roaring away; more often than not there is quite enough noise in the engine-room without the aid of the boiler-house.

The rule allowing a margin of 5 lbs. does not hold good if the safety-valves are not tight on their seats. A badly seated valve will blow considerably below the working pressure.

These valves require grinding in with fine emery powder from time to time.

The operation is one which needs a fair amount of skill, and should be done by a mechanic—not the fireman.

The practice of putting weights on the lever of a safety-valve, in order to prevent steam escaping, is not only useless, but dangerous. Grinding in is the only remedy.

A disadvantage of lever safety-valves is that they may be tampered with in this way; but with spring-loaded valves, when once set and locked up, they cannot be altered in any way, and should a particle of dirt get between the valve and seating, causing steam to blow, a slight twist of the spindle will often stop it.

The blow-out apparatus is sometimes responsible for a good deal of waste. When a boiler is laid off

* From *Electricity*, London.

for cleaning, etc., the blow-out cock should be examined, and if necessary, ground in.

If the plug leaks it will be corroded and show signs of unequal wear. Before replacing the plug after grinding in, it should be rubbed over with black-lead and tallow, as this greatly facilitates its working when in use.

The waste pipe from the blow-off cock should be placed where any leakage can be detected.

The undue formation of scale and neglect in cleaning a boiler is another source of waste. Every engineer knows that a certain amount of scale is beneficial to a boiler, as it protects the plates from the injurious effects of impure feed water; but when it becomes too thick it not only wastes fuel, but may cause the furnace crowns to overheat.

A boiler should be laid off for inspection about every month or six weeks, all superfluous scale removed, and flues cleaned.

Soot is a non-conductor of heat, and therefore fuel is wasted when the flues are dirty.

Bad firing means waste of fuel.

Men are sometimes employed who are mere novices at firing, with the result that they waste a large quantity of good fuel, especially when cleaning fires. It is far better to engage men who are experienced.

Leaving the boilers, waste may be looked for in the following: (1) Leaky joints; (2) steam traps; (3) leaky slide valves and glands; (4) running large engines underloaded.

Joints are often allowed to blow until they get so bad that they are nuisances, drowning any noise about the machinery which may warn the man in charge that something is wrong. When a joint begins to blow it might as well be made at once, for it's only a matter of time till it becomes a necessity. A good joint for steam piping is a corrugated metallic ring, spread with putty or cement.

The disadvantage of using asbestos is that unless a joint is screwed up once or twice after making, the expansion and contraction of the steam piping is apt to loosen it and it soon begins to leak again.

Asbestos is more suitable for covers, blank flanges, etc. Steam traps frequently do more than is required—they pass steam in addition to water.

A far more economical arrangement is an interceptor or catch-water. This consists of a vessel fitted with a plate three-quarter way down the middle. The water coming through with steam impinges against the plate and falls to the bottom, the steam passing down under the plate and out at the top on the other side. The vessel is also fitted with a water gauge and drain cock. Every now and again the water is blown out into the feed water tank. Leaky pistons and slide valves are often met with, due to the fact that they are not looked after to the same extent they should be.

Speaking generally, there seems to be a want of mechanical knowledge in central stations, and the common impression is that as long as the electrical portion is all right it does not matter about the mechanical part. But here is a grand mistake—the mechanical is the more important part. It has been said, and not without reason, that a man is an engineer first and an electrician after.

Leaky valves not only waste fuel, but they upset the governing arrangements of an engine. In a compound engine the steam passes the valve into the low-pressure side, causing this side to do more work than it would if the slide valve was steam tight.

An engine should be indicated periodically, and if the slide valve leaks it will be seen by the expansion line on the card rising, instead of falling gradually to the point of cut-off.

The remedy in this case is to reface the valve, or if a piston valve, to fit new springs or reline valve chamber.

The practice of running large engines at light loads is to be condemned. As soon as the load falls to the full output of the next size set, it should be thrown on to it. If there is any doubt about the engine being unable to do the load for which it was designed the engine ought to be tested, the sooner the better.

The causes of waste of fuel in central stations recited above do not cover the whole of the ground. It would be absurd to attempt to do so exhaustively here; but it is intended to show the waste which very often goes on during the ordinary running of a station.

Much might be written on waste due to bad design, but that would be opening up fresh ground, and altogether out of the scope of the present subject. When plant has once been laid down it is rather a difficult as well as an expensive matter to rectify errors of judgment.

ELECTRICITY IN AGRICULTURE.

In the *Electrotechnische Zeitschrift* of October 20, says the *Electrical Review*, London, two successful installations of electric plowing are described. According to the figures given, the cost of electric plowing compares very favorably with the cost of steam plowing, at least in Germany.

In the first case described, a farm (Dahlwitz by name) is supplied with its whole light and power from a central station of 60 HP. For lighting, an alternating current at 1,000 volts is used, the voltage being transformed down at the place where it is consumed; while for driving pumps, threshing machines, plows and other machinery, a direct current of 500 volts is utilized. Herr v. Treskow, the owner of Dahlwitz, estimates the total consumption of energy to be 111,300 HP. hours per annum, about half of which is used to work the electric plow; 250 acres are plowed per annum, and the cost, according to Treskow's calculation, is 31s. 3d. per acre, which is considerably cheaper than steam plowing.

Experiments on the royal demesnes, Sillium and Cloeden, have led to similar results. A communication by the Minister of Agriculture to the members of the Prussian House of Delegates, puts the cost of electric plowing in heavy soil, with deep cultivation, at 45s. to 55s. per acre, and that of steam plowing at 85s. per acre. Besides this reduction in the cost of plowing, it is to be remembered that power required for other purposes on the farm is reduced in cost to almost the same extent.

The system employed at Dahlwitz is the so-called single machine system, and was installed by F. Brutschke, of Charlottenburg. The mechanical apparatus was made by the firm of Borsig. The 500-volt direct current is carried by aerial lines between the fields, and at suitable places on the poles are couplings for connecting up the movable cables which lead the current to the motor. Cable drums are not used, the redundant length of cable being laid by hand in large coils on two carriers fixed on the motor wagon. The motor wagon contains a motor which drives the winding drums, and which can also be coupled to the driving wheels of the wagon, to give it the necessary advance at the end of each traverse of the plow. The rope (15 mm. diameter) runs off one drum in the direction of motion of the plow to the other end of the field where it passes round a loose pulley and then back to the second winding drum on the motor wagon. The rope winds itself on to one drum and off the other till the plow comes to the end of the furrow.

Of course during the approach of the plow the tension on the loose pulley is double that on the rope, and the wagon on which the pulley is mounted must be very firmly anchored. This is done by means of an anchor with four prongs, which bury themselves deep in the ground when the tension comes on the rope. While the plow is on its return journey in the direction of the motor wagon the loose pulley is almost entirely free from tension, and advantage is taken of this to pull the anchor out of the ground by screw gearing driven from the loose pulley. A second coupling then throws the loose pulley into gear with a small drum, which winds on an anchored rope, and causes the pulley wagon to advance a step into position for the next furrow. The attendant then disengages the coupling, and allows the main anchor to fall down. As in steam plowing, the motor wagon is advanced at the end of each traverse by coupling the motor to the driving wheels. Three men are required to attend to the plow. The depth of the furrow was 20 to 25 cm., the width about 130 cm., and the speed of plowing 1 meter per second. The consumption of current in the central station varied from 30 to 50 amperes at the 500 volts.

Electricity in Italy.

According to *L'Elettricita*, electricity as a motive power is rapidly being adopted for various purposes in Italy. At Naples the construction of an electric street railway is progressing rapidly which when completed will connect the Museum and the Toretto. This it is claimed is the first step towards the transformation of the whole Neapolitan street railway system—a matter which will shortly be considered by the Municipal Council. The municipal authorities of Savona have petitioned the Postmaster-General to connect their town with Genoa. A company has been formed in Turin for the purpose of building an electric trolley line from Varallo to Aragna. Another company has been formed in Bologna for the purpose of manufacturing and distributing current for lighting and motor purposes. The Mediterranean Railway Company is going to try electricity on its lines. The first trials will be made on the line from Milan to Gallarato and the three branch lines to Arona, Varese and Laveno. In all 34 applications have been made for water power for the generation of electrical current; 29 of these have been granted, as being able to supply that demand without damaging other interests. From the above it will be seen that electrical undertakings are flourishing in sunny Italy.

Incandescent Lamps and Coal Mine Explosions.

In the *Revue Industrielle* of October 29, Messrs. H. Couriot and J. Meunier describe some interesting experiments in which known mixtures of air and methane, similar to the well-known "firedamp," are introduced into electric incandescent lamps. In the case of 10 CP. lamps, the current being equal to 0.8 ampere, and the pressure to 45 volts, the filament almost instantaneously ceased to be luminous, except at a certain point where a rupture occurred soon afterwards, accompanied by a minute spark. No explosion was produced. Similar results, says the *Electrical Engineer*, London, were obtained with lamps carrying greater currents. The authors explain these results in consonance with a former communication, wherein it was shown that incandescent metallic filaments are powerless to produce explosions even in the most explosive mixtures.

Connecticut Street Railway Association.

The 4th annual meeting of the above Association was held at New Haven on the 16th inst. The meeting was interesting, one of the questions discussed being that of protecting their interests in the event of any legislation detrimental to street railway progress or prosperity. The officers elected for the ensuing year were as follows: President, Henry S. Parmelee, Fair Haven and Westville Railroad Company; vice-president, Congressman E. J. Hill, Norwalk Street Railroad Company; treasurer, E. S. Goodrich, Hartford Street Railroad Company; secretary, B. W. Porter, Derby Street Railroad Company; executive board: President Parmelee, Vice-President E. J. Hill, A. M. Young of the Waterbury Traction Company, C. S. Treadway of the Bristol and Plainville Tramway Company and A. W. Mather of the Central and Electric Railroad Company, New Britain.

MR. TESLA AND "THE ELECTRICAL ENGINEER."

New York, Nov. 18, 1898.
46 and 48 E. Houston St.

Editor ELECTRICITY.

DEAR SIR: Under inclosure I forward you a copy of a letter which is self-explanatory. If you consider it a justice to me to insert it in your next issue, kindly do so. Yours very truly,

N. TESLA.

[INCLOSURE.]

New York, Nov. 18, 1898.
46 and 48 E. Houston St.

Editor of the *Electrical Engineer*,
120 Liberty St., New York City.

SIR: By publishing in your columns of November 17th my recent contribution to the Electro-Therapeutic Society you have finally succeeded—after many vain attempts made during a number of years—in causing me a serious injury. It has cost me great pains to write that paper and I have expected to see it appear among other dignified contributions of its kind, and, I confess, the wound is deep. But you will have no opportunity for inflicting a similar one, as I propose to take better care of my papers in the future. In what manner you have secured this one in advance of other electrical periodicals who had an equal right to the same, rests with the secretary of the Society to explain.

Your editorial comment would not concern me in the least, were it not my duty to take note of it. On more than one occasion you have offended me, but in my qualities both as Christian and philosopher I have always forgiven you and have only pitied you for your errors. This time, though, your offence is graver than the previous ones, for you have dared to cast a shadow on my honor.

No doubt you must have in your possession, from the illustrious men whom you quote, tangible proofs in support of your statement reflecting on my honesty. Being a bearer of great honors from a number of American universities, it is my duty, in view of the slur thus cast upon them, to exact from you that in your next issue you produce these, together with this letter, which, in justice to myself, I am forwarding to other electrical journals. In the absence of such proofs, which would put me in the position to seek redress elsewhere, I require that, together with the preceding, you publish instead a complete and humble apology for your insulting remark which reflects on me as well as those who honor me.

On this condition I will again forgive you, but I would advise you to limit yourself in your future attacks to statements for which you are not liable to be punished by law.

N. TESLA.

[The editorial of the *Electrical Engineer* referred to in the above letter is reproduced below, and we give it space as an act of justice to the parties concerned and for the enlightenment of our readers as to the character of the offence charged.—ED. ELECTRICITY]:

MR. TESLA AND THE CZAR.

The personality of Mr. Tesla is one of the most fascinating in the field of modern invention, and his work is such as to command the interest of both the lay and the scientific public whenever he chooses to give details of his investigations and researches. If he had never done more than develop the theory and practice of the multiphase system, his life would have been useful above the ordinary; and even should it happen that none of his other ideas ever get into practical shape, his discoveries in electricity must always be regarded as important. We cannot number ourselves among those who, like the distinguished scientists, Profs. Brackett and Dolbear, quoted in our columns this week, are impatient with his tendency to let imagination outrun achievement and who virtually class him as a humbug. Mr. Tesla fools himself, if he fools anybody, when he launches forth into the dazzling theories and speculations associated with his name. That he should desire to benefit the human race in ways now unknown, and should avow out loud belief in his capacity to do so, is surely not discreditable, any more than it is unworthy in the head of his own poetic Slavic race to propose the disarmament of the world. Granted that there will still be wars, and granted that all these wonderful visions of new arts in peace do not fructify without the work of a score of later geniuses, why find fault either with the Czar or Mr. Tesla? Their aims appear wholly noble, their thoughts are beautiful, and if they fail, as they probably will in some material and vital respects, the world is certainly none the worse off for what they actually accomplish.

Just of late Mr. Tesla has been giving publicity to some of his newest work, and it is peculiarly interesting. We should have been glad, personally, to see him finish up some of the many other things that have occupied his energies these ten years past, but none of which now claim any place. For example, his "oscillator," or combination of generator and steam engine, which was to wipe out all other methods of power generation and reduce vastly the cost of power, by steam and electric economies. The very name is now bestowed by Mr. Tesla on another piece of apparatus, and though illustrated in detail and brought before the Chicago Electrical Congress in 1893, the "oscillator" of the original brand is, for aught the public knows, in the scrap heap. Yet it was a lovely invention, of infinite possibilities. We can only regret its neglect and oblivion, but if Mr. Tesla has other things more appealing to his mind for the present, that is his own business.

Of late also Mr. Tesla has brought forward another plan of power generation and transmission. At one period he expressed his belief in ability to disturb the earth's charge and thus send currents through the earth. That does not appear to be so feasible or attractive now as the idea of using the upper strata of the air which he says have a very superior conductivity. He would tether up aloft balloons in those strata and deliver to them large quantities of current at such high potential that it would travel economically across the space without wires, say from Niagara Falls to Paris. By this facile distribution of water power, coal and steam would become unnecessary to industry. The new plan may explain why Mr. Tesla has abandoned his old steam oscillator. It is earnestly to be hoped that this novel idea will prove workable. Balloons were a dismal failure in our late war, but that is no criterion, and Mr. Tesla may have some superior gas for inflation and sustentation purposes. It will be remembered that Mr. Marconi has already telegraphed from balloon to balloon, without wires, a distance of over twenty miles, thus proving in advance the tenability of Mr. Tesla's proposition.

The tremendous hold that war has taken upon the public mind is shown by the fact that even a genius of Mr. Tesla's independence is compelled to invention in that field. A patent issued to him last week intimates that he believes that torpedoes and torpedo boats, which were so utterly useless and unmanageable in the late conflict with Spain, can be made more valuable if controlled entirely from shore, by a Navy Board, and without any crew. Last spring the ability to explode floating torpedoes under ships from a distance without any wires was brilliantly demonstrated at Madison Square Garden several times a day for a month. Taking that idea, Mr. Tesla has applied the same principle to the electro-mechanical steering of torpedoes, just as it is now done with several types, but, of course, in his case, without the intervening wires from shore. He is very sanguine that this will stop war, and we pray heartily that it may. The article or patent digest we print in this issue on the subject suggests improvements of his on existing apparatus that may render it, in spite of its great delicacy, able to evade jarring and jolting, the perils of the open sea, the defensive network crinolines around the ships, the concussions of great guns, and the intentional explosion of defenses placed in its way thus to derange and negative its operation. During the late war apparatus far less sensitive than coherers was rendered useless by the firing of the heavy artillery on the ships, and it must be a preternaturally tough coherer that would escape the same fate. So also it must be a very difficult problem for which Mr. Tesla cannot suggest half a dozen diagrammatic solutions.

While all these curious things are "in the air," so to speak, it is a distinct pleasure to be able to print, as we do in this issue, Mr. Tesla's able and thoughtful paper read before the Buffalo meeting of the American Electro-Therapeutic Association. It compensates for the disappointment experienced from his unfinished lecture two years ago before the New York Academy of Sciences, which has never found its way into print, but of which the opening passages indicated the covering of the same ground. We trust that the data given by Mr. Tesla may stimulate our medical friends to greater employment of electricity. It is unfortunately true that disastrous results from injudicious use by some of them of Prof. Roentgen's great discovery of the X-ray have made medical men fight shy of handling electricity themselves lately, and we do not know whether Mr. Tesla's experiments will altogether reassure them, so striking and far-reaching are they. But the saving of human life is a sacred thing. Every means and instrumentality must be tried by the surgeon and physician, and it is devoutly to be hoped that having stopped the slaughter due to war Mr. Tesla will revert at some time to this brilliant paper and give the doctors apparatus that will help prevent the slaughter due to accident and disease.

It is not our desire to pose as apologists or publicists for Mr. Tesla. He needs no assistance of that kind; and so long as he commands freely whole pages of the Sunday papers, for which Mr. Wanamaker pays gladly his thousands of dollars, the technical and scientific journals have, indeed, little to do with the matter. All we wish to say is it is not fair to condemn, as so many do, Mr. Tesla as visionary and impractical. No man has finished his work till he is dead, and even then there are long, long centuries in which his ideas can prove themselves true. The visionaries are thus often, in the end, the most sordid of realists—something Mr. Tesla will never be.

Meeting of the American Institute of Electrical Engineers.

The 129th meeting of the American Institute of Electrical Engineers will be held at 12 West 31st street, New York City, on Wednesday, November 23, at 8 o'clock P. M. A paper will be presented by Frederick W. Carter, of London, Eng., on "The Design of Transformers."

Applications have been received from the following candidates for associate membership, which will be acted upon by the Executive Committee at its meeting December 28, 1898:

Robinson Crowell, Schenectady, N. Y.
W. N. Gladson, Fayetteville, Ark.
William B. Hodge, Philadelphia, Pa.
Francis E. Tyng, New York City.
John C. Finney, Milwaukee, Wis.
G. H. Hill, Bloomfield, N. J.
John Allan, Sydney, N. S. W.
Arthur J. Wood, New York City.
Henry B. Dates, Potsdam, N. Y.
Leo Walter, Hildburgh, N. Y.
J. J. Bellman, Ampere, N. J.
Saitaro Oi, Tokyo, Japan.
Lincoln S. Risley, New Britain, Conn.

ELECTRIC ROADS NEEDED IN PORTO RICO.

Gen. Roy Stone, United States Volunteers, who recently returned to Washington from Porto Rico, where besides fighting with his troops he made a very thorough investigation of the roads on the island. He is reported in a Washington dispatch to the *Sun* as saying:

"I am convinced that Porto Rico will never have a complete system of wagon roads such as some of the States have. Roads are enormously expensive in that island, the celebrated military road costing in the neighborhood of $100,000 per mile. The enormous rainfall distributed throughout all seasons is ruinous to any road unless thoroughly well drained and constructed on a hard foundation. I believe, however, that the place of the wagon roads will be more than filled by electric roads, of which I am certain there will soon be a network over the island. Steam railways would be too expensive to construct or to operate, there being no coal on the island, while there is an abundance of water power. The rivers rise in the mountains in the interior and have an average fall of 2,500 feet in their short race to the sea, and there is always abundance of water pouring over high falls. Power for electric roads could be obtained from these falls at little expense, the roads could be easily graded and the rain would not affect an electric road as it does a wagon road. These roads would open communication between the interior and the coast and place the coffee, sugar and tobacco of the plantations within easy access of the seaboard. I regard the possibilities for the investment of American capital in Porto Rico as something immense. Porto Rico is destined to outstrip Cuba in the next few years. In addition to having a more stable government its climate is better, its people more peaceable and better workmen, and its soil fully as fertile. The Porto Rican laborer resembles the Italian of the same class. He is cheerful, industrious and economical, and his labor is very cheap, about one-fourth that of an American laborer. This is explained by the fact that food and clothing cost but very little on the island. The laborer lives on the fruit of the banana tree, which also furnishes partly his clothing and housing. He needs little furniture and little clothes. The educated natives are a high class of people, cultivated, polite, and compare favorably with the higher classes in the States. The lower classes are capable and willing to learn. They are all very friendly, and almost every one on the island is attempting to learn English. They are especially desirous of having American schools established or having the English language taught in the schools.

"With cheap labor and free access to American markets, railroad facilities and plantations owned and operated by Americans, I fail to see anything but a brilliant future for the island. The sugar, coffee and tobacco, the banana and cocoanut plantations, electric railroads and paper making are all good enterprises in which capital can be properly invested. There is little doubt that in a few years Porto Rico will be the winter resort of America. Its climate is equal to that of Florida or Cuba in the winter time, its atmosphere more healthful and its scenery far more varied and interesting. In addition to all the tropical luxury of vegetation, Porto Rico has high mountains, beautiful valleys, splendid waterfalls and beautiful views. As the electric roads open up communication with the interior it will be possible for the tourist to visit all the show places of the island at his ease, and with American hotels or boarding houses scattered over the island he can always get good accommodations. Within a year there will be a number of fine hotels at San Juan and Ponce and preparations made for the influx of winter tourists."

In conclusion, Gen. Stone said that owing to the density of the population of Porto Rico and the cheapness of living, it would be a long time before wages reached the American scale, but as the demand for Porto Rican products increased, the demand for labor there would advance the price of it, and gradually, as the laborer became accustomed to the comforts of the American laborer, he would need more and receive more. He believes that matters in Cuba will be unsettled for several years at least, during which time he thinks the conservative American capitalists will invest their money in Porto Rico rather than in Cuba. Gen. Stone will make a report on the result of his inquiry to the Secretary of War.

New York Electrical Society.

The 191st meeting of the New York Electrical Society was held on Thursday evening, November 17, at the College of the City of New York. An interesting and lengthy paper was presented by Mr. E. H. Johnson, entitled "Surface Contact Railways, with special reference to the Johnson-Lundell System." The meeting was unusually well attended. The following is a list of new members elected at the business meeting of the Society:

Prof. J. Burkitt Webb, Stevens Institute, Hoboken, N. J.
Hubert Greaves Webb, Glen Ridge, N. J.
Henry V. Parsell, New York.
Joseph White Stickney, Brooklyn, N. Y.
August Treadwell, Jr., Electric Storage Battery Co., New York.
Morton Arendt, New York.
W. G. Burns, New York.
Theo. H. Joseph, New York.
Bernhardt Hoffman, N. Y. Telephone Co., New York.
W. I. Thompson, Newark, N. J.
Frank R. Wainwright, Chesley Electric Co., New York.
Thomas J. Buckley, Tenafly, N. J.
St. John P. Chilton, New York.
William Newton Ryerson, Montclair, N. J.
Thomas J. Fay, Electrical Engineer School of Correspondence, New York.
J. E. Woodbridge, Editor *Electrical World*, New York.
Charles E. Dustin, Excelsior Electric Co., Brooklyn, N. Y.
Henry B. Cutter, Philadelphia, Pa.
Alexander McGill, New York.
Charles T. Child, Electrical Editor *Engineering Magazine*, New York.
Lieutenant W. D. Weaver, *American Electrician*, New York.
Dr. Louis Duncan, Empire Building, New York.
A. E. Clifford, *American Electrician*, New York.
A. Stamm, Chesley Electric Co., Hoboken, N. J.
V. C. Gilpin, Cutter Electric & Mfg. Co., New York.

LEGAL NOTES.

An injunction has been issued by Judge Tuthill of the Circuit Court at Chicago, at the instance of the former stockholders of the Merchants' Arc Light & Power Company, restraining the Chicago Edison Company and Samuel Insull, its president, from proceeding further in paying William H. Collins, secretary of the Merchants' Company, for the stock of that company, alleged to have been purchased by the parties enjoined. The order of the court also forbids William H. Collins from disposing of or in any way incumbering the money and contracts already received by him in the sale till the further order of the court. At a meeting in January, 1898, it is said, some of the stockholders of the Merchants' Company declared their willingness to sell their stock for $15.40 per share of the par value of $100. Collins, it is declared, told the shareholders that such a price might be obtained if the entire stock of the concern were placed upon the market, and agreed to find a purchaser. In April, the shareholders say, they were informed by Collins that he had a buyer, and they accordingly relinquished their shares on the receipt of $15.40 per share. Since the sale the shareholders assert they have discovered that a much higher price was obtained by Collins for the stock than he led them to believe was possible. The claim of the petitioners now is that Collins received $25,000 for the stock, or about $72 per share.

The Marks Enclosed Arc Light Company has been granted a perpetual injunction in the United States Circuit Court at New York, restraining the Electric Construction & Supply Company from further infringing the former company's patent for an improvement in arc lights. The order of the court decrees that the Marks Light Company owns the exclusive right to United States letters patent No. 520,996, granted to Louis B. Marks and Clarence Ransom, in June, 1894, and that the defendant company has infringed that patent by making and selling lamps similar to those made by the plaintiff, and known as the "Kinsman," the "Kinsman 150 hour lamp," and the "Kinsman long burning arc lamp."

Justice Collins filed an opinion in the Supreme Court at Trenton, N. J., last week which sustains a verdict for damages secured in the Essex Circuit against the Newark Electric Light & Power Company, on account of Thomas J. Ruddick, an 8-year-old child, who was injured by taking hold of a live wire that was trailing on the street. The case was carried to the Supreme Court on an exception to the refusal of the trial Judge to grant a non-suit. The non-suit was asked for on the ground that there had been no negligence on the part of the company, that the wire had been down but a few minutes. Justice Collins's opinion holds that the length of time the wire was down does not enter into the case, and the company did not avail itself of the opportunity to prove that the breaking of the wire was due solely to the elements and not within the company's power to prevent.

Papers were filed in the office of the clerk of the United States Circuit Court at Brooklyn, N. Y., on the 18th inst. by the Thomson-Houston Electric Company in an action against the Nassau Electric Railroad Company to enjoin the latter company from using a certain electric commutator or switch and also for the appointment of a commission to determine damages from alleged unlawful use of the switches.

THE NEWS.

What is Going On in the Electrical World.

LIGHTING.

Camden, N. J.—The Lighting Committee of the council met on the evening of the 16th inst. to open bids and award contracts for lighting the city with arc and incandescent electric lights from July 1, 1899. Previous to opening the bids an order was read from Judge Garrison, citing the members of the council to appear before him on November 26, and show cause why a writ of certiorari should not be granted, reviewing the action of council in granting a franchise to the Citizens' Light, Heat & Power Company, that company having put in a bid. The rule was granted in a suit of John M. Kelly and others, representing the Camden Lighting & Heating Company.

Kazabazua, Can.—A joint stock company is to be formed shortly to establish an electric light plant here. The company will put in lights at a very low figure in order to encourage the residents to patronize this new enterprise.

Kissimmee, Fla.—J. M. Bailey having proposed to the council to put in an electric lighting plant in this place, that body has decided to call a special election for the purpose of voting on the proposition of granting a ten-year exclusive franchise to Mr. Bailey for lighting the town.

Kokomo, Ind.—The electric light plant of the Citizens' Light & Power Company of this city was sold at receiver's sale on the 12th inst., Woodruff & Stevens of Detroit being the purchasers. They are the principal owners of the Kokomo Street Railway Company. The price paid was $24,000. The plant cost $70,000.

Louisville, Ky.—An electric light plant is to be placed on the steamer Kate Adams, the first of the kind put on a steamboat on the Ohio.

Newton, Kan.—The plant and franchise of the Newton Light & Power Company have been purchased by a company which will be known as the Gas & Electric Company of Newton. The institution is now entirely in the control of Newton parties. The officers are: Don Kinney, president; John C. Nicholson, vice-president

and treasurer; James D. Nicholson, secretary. The plant will be improved and enlarged.

Ogdensburg, N. Y.—An electric light plant is to be erected at St. Regis Falls if the residents agree to take lights enough to warrant the undertaking. A canvass is being made to determine this question.

Omaha, Neb.—The J. C. Hubinger Company of Keokuk, Ia., has made application to the city council for an ordinance granting it the right to maintain and operate a steam heating plant and an electric light and gas plant in Omaha. The company offers, if the ordinance is granted, to furnish the city offices with steam heat and incandescent light free of charge, the lights to be burned such hours as would be agreed upon between the company and the city.

Providence, R. I.—The enclosed arc lamp is rapidly coming into use in the large dry goods stores of this city; in one store here 124 enclosed arc lamps are distributed throughout the different departments. The light given is described by the "Providence Journal" as the most satisfactory substitute for sunlight in millinery and fine dress goods departments that has ever been brought to the attention of the users. The lamps are very cleanly and reliable in operation, do not scatter carbon dust, are ornamental in appearance and give an evenly diffused light.

Salem, Mass.—The Salem Electric Lighting Company is adding to its plant two Edison bi polar generators, each of a capacity of 2,000 lights of 16 candle-power. This addition is made to meet the increased demand for light and power.

Sarcoxie, Mo.—The Sarcoxie Electric Company has been organized to build an electric light plant.

Savannah, Ga.—The probability is that Savannah will soon have two underground electric lighting systems. The holding up of the new Edison Illuminating Company's ordinance for the purpose of considering that of the Brush Company at the same time, is understood to mean that both will be treated alike. The Brush Company has been contemplating establishing the underground system for some time.

Schaghticoke, N. Y.—The board of trustees has granted the Valley Electric Light Company the privilege of erecting poles and stringing wires throughout the village for electric lighting purposes.

Schuylkill Haven, Pa.—An explosion at the borough electric plant on the 12th inst. badly damaged the dynamos and other machinery, and left the town in darkness.

Sturgis, Mich.—The question of erecting a municipal lighting plant was decided in the affirmative at a special election held here on the 11th inst.

St. Paul, Minn.—The specifications for street lighting submitted by the board of public works to the council committee on streets provide for the lighting during 1899 of electric arc, gas and gasoline street lamps and for public buildings. The specifications provide for 375 electric arc street lamps, which is an increase of 118, there being 257 now in use. The company securing the electric lighting contract, according to the specifications, will be awarded a franchise to do a commercial business for ten years within the district covered by its contract. This question will be thoroughly discussed by the council and may be materially changed, as it is understood there is some opposition to it.

Thibodaux, La.—The proposition providing for an extra tax to establish and maintain an electric light plant was carried at the recent election by a large majority.

Urbana, O.—The electric light plant in this city, heretofore owned by Chicago capital, has been purchased by a new local company of which Frank Chance is president and John C. Powers secretary and treasurer.

Warrens, Wis.—The George Warren Company has decided to put in an electric plant here for public and private lighting, and with that object in view has invited Mr. Benton, an electric light expert from La Crosse, to come and submit a proposition to furnish and install the plant.

STREET RAILWAYS.

Bennington, Vt.—A bill consolidating the Bennington Electric Railroad Company and the Hoosick Electric Railway Company has passed both branches of the Vermont Legislature. The two roads have, however, practically been consolidated for some time past.

Belfast, Me.—The building of an electric road from this city to Northport is being agitated anew, and with some prospect of the scheme being carried out. A charter for the road, secured some six years ago, has been renewed from time to time, and is held by the original incorporators. These are Charles B. Heseltine, president of the Belfast & Moosehead Lake Railroad; William B. Swan, ex-mayor of Belfast; Asa A. Howes, a prominent merchant and director in many corporations; Dr. John G. Brooks, president of the Belfast National Bank; N. F. Houston, president of the Savings Bank; John H. Quimby, cashier of the Savings Bank; James H. Howes, a prominent business man; Hon. E. K. O'Brien of Thomaston; Hon. H. L. Shepherd and his brother Edward of Rockport.

Burlington, Vt.—The contract for the construction of the electric railway between this city and Hinesburg has been let to C. W. Blakeslee & Sons. The road is to be 15 miles long and will be used for freight as well as passenger traffic.

El Paso, Tex.—An ordinance has been adopted by the city council granting to B. F. Hammett, Moses Dillon and associates a franchise to construct, maintain and operate lines of electric street railway in this city and to establish an electric plant for the purpose of furnishing light, heat and power. The term of the franchise is fifty years. The grantees are required to put up a forfeit of $10,000 to have both plants complete and in operation within two years from the date of the deposit.

Hackensack, N. J.—The Bergen Traction Company will not be able to reach Hackensack this winter, owing to the fact that permission from Congress must first be obtained before a bridge can be built across the Hackensack river near the spot in Hackensack where the company purposed making its terminal. The grading of the remainder of the road is completed from Leonia to Bogota.

Houghton, Mich.—The village council has voted to give a franchise for a street railway to William H. Taylor of New York, provided he can secure franchises from other towns so as to build a belt line about the county, connecting Houghton, Hancock, Quincy, Franklin, Dollar Bay, Lake Linden, Laurium, Calumet and Red Jacket. The proposed line will be twenty miles long.

Kittanning, Pa.—F. A. Maesta is president of the company which is building the electric road between Ford City and Kittanning.

Jersey City, N. J.—The North Jersey Street Railway Company has arranged for a new trolley line extending from Communipaw avenue to a point near the boundary between Greenville and Bayonne, where it will intersect the company's main line. The line will be a great convenience to people living in the southern section of Jersey City.

Lewiston, Me.—The controlling interest in the Lewiston, Brunswick & Bath Street Railway has passed into new hands at a cost of nearly half a million dollars.

Lexington, Ky.—A company is being formed in this city to build an electric railway between Lexington and Richmond, Ky., 22 miles. The principal promoters are W. J. Loughbridge, vice-president of the Electric Street Railroad Company, and Dr. Bennett, president of the National Exchange Bank. The road will cost $125,000 and will cross the Kentucky River at Clay's Ferry.

Miami, Fla.—There is a movement on foot for the building of an electric railway from Miami south to Cutler and north to Lemon City.

Needham, Mass.—The selectmen have granted a franchise to the Needham & Boston Electric Railway Company to lay tracks and operate a line of electric street cars between Postoffice square, Needham, and the Dedham town line, via Great Plain, Dedham and Harris avenues. The company proposes to connect at Spring street with the West Roxbury and Roslindale company and will give a 10-cent fare to Boston.

Owosso, Mich.—Eastern capitalists and local owners of the road and power plant of the Owosso & Corunna Traction Company are planning to extend their road to this city from Flint, extending the electric lines running west of Detroit to the Pontiac and Sylvan road. Grand Rapids and Chicago capitalists are also endeavoring to secure the property to construct lines through to Grand Rapids and Lansing. This will make Owosso the center of all the electric roads in this part of the State. The capital interested is $400,000.

Pine Bluff, Ark.—A committee of citizens is securing subscriptions here for an electric car line and lighting plant on a plan submitted by Henry C. Wood, representing the Westinghouse Company. The subscription proposes a company capitalized in the sum of $300,000 with $200,000 subscribed in bonds, the par value of each being $1,000; sixty, with a par value of $500 each; 200 with a par value of $100 each. It is proposed to have assigned to the company the franchise granted to Nat Covington and Wilbur C. Harrison, and to have as officers of the company Col. S. W. Fordyce president, the vice-president, secretary and treasurer to be citizens of Pine Bluff.

Rochester, N. Y.—The directors of the Rochester & Irondequoit Railroad Company, better known as the Bay Railroad, have decided to lay double tracks over their road and to equip it with electric cars before another summer season opens.

Rockland, Mass.—Pepper & Register of Philadelphia, who recently came into possession of the Rockland & Abington Street Railway, have obtained a controlling interest in the Bridgewater, Whitman & Rockland line. It is said that Pepper & Register are leaders in a project for amalgamating all the street car lines in Southeastern Massachusetts.

Rockaway, L. I.—The Queens Borough Electric Light & Power Company is erecting a big power house at Far Rockaway for the purpose of supplying power for the operation of a trolley line running the whole length of the Rockaway peninsula for which franchises have already been secured. This line, it is said, is intended as a feeder for the Long Island Railroad, and will connect with the Brooklyn Elevated at Woodhaven. The plant will be equipped to furnish light as well as power, and the company proposes to erect docks and a coal elevator in connection with the power house. Van Wyck Rossiter is president of the company and R. C. Peabody vice-president.

Salem, N. Y.—J. S. Powers of Lansingburg has surveyors at work examining a route for an electric road from Schuylerville to Salem via Greenwich and East Greenwich.

Sidney, N. Y.—The name of the Delaware Terminal Company has been changed to Delaware Electric Light & Power Company. The company has a large force at work on their trolley road which is to connect this place with Franklin. The power house will be erected midway between Franklin and Sidney.

South Bethlehem, Pa.—Capitalists are securing the right of way for an electric road from here to Nazareth, a distance of eight miles. After this line is completed the road will be extended twelve miles to Wind Gap, Penn Argyl and Bangor, and from there another twelve miles to Portland and Delaware Water Gap. The railway which connects South Bethlehem with Hellertown will be extended to Quakertown, and the line from Quakertown to Doylestown will be completed. The near future will therefore see direct communication by electric railway between Philadelphia and the Delaware Water Gap, a distance of about eighty miles.

St. Louis.—The bond of $50,000 of the Lindell Railway Company to secure the franchise extension recently granted the company by the municipal assembly has been approved by the council. The sureties on the bond are Edwards Whitaker, Charles D. McLure, Henry D. Haarstick and S. M. Dodd.

Washington, D. C.—The Belt Railway was bought at public auction on the 15th inst. by Oscar T. Crosby for $350,000. The sale includes the franchises, real estate, rolling and live stock of the old company. An underground electric system must be installed within one year from the date of the ratification of the sale by the court.

Zanesville, O.—It is learned from what is deemed a reliable source that the Zanesville Street Railway & Electric Light Company will be taken out of the receiver's hands and the company reorganized in a short time.

MANUFACTURING, ETC.

Ansonia, Conn.—The Russell-Tomlinson Electrical Company, manufacturers of electrical specialties and novelties, has reorganized under the same name, with an increase in capital stock from $10,000 to $17,000 in shares of $100. The officers of the new company are: President and general manager, William Russell; vice-president, William Tomlinson; secretary, George G. Milne. The company will purchase an entire new outfit of machinery and double the size of the factory.

Fort Wayne, Ind.—A rumor having got abroad here that the Fort Wayne Electric Corporation was to enter the electrical combination formed by the Westinghouse and General Electric companies, President R. T. McDonald was questioned in regard to the matter and replied: "No, there is nothing in it at present, but one can't say what might happen in the future. It is true that the corporation has been talking for some time past of raising money with which to erect additional buildings, but I do not know that that should have started the report. We need more room here and want to build some additions as soon as we can manage it."

POWER AND TRANSMISSION PLANTS.

East Helena, Mont.—The smelter plant here is now being operated by electricity transmitted from the Canyon Ferry electrical plant. It is related as an evidence of the promptness with which the work was done when everything was made ready that the blast furnaces were shut down but four hours while the steam power was being cut out and the electricity installed. There are a number of motors, two of 175 horse-power each, and three of 100 horse-power, one of 50 horse-power, one of 30 horse-power and one of 20 horse-power.

Grand Rapids, Mich.—The Newaygo Transmission Company has been organized by local capitalists, with $15,000 capital, to develop the water power at Newaygo, thirty miles north of here, and to transmit electric power to this city. The company has been given a franchise to erect poles and string wires in this city. A. C. Sekell and Charles F. Pike are the chief promoters of the enterprise.

Lindsay, Can.—Some time ago Messrs. Culverwell & White-Fraser of Toronto undertook to form a company and transmit power from Fenelon Falls to Lindsay, but could not carry out the undertaking. The matter has been taken up by some of the citizens, with A. E. Ames of Toronto. An electrical expert is to be employed to look into the matter, and if the scheme is endorsed by him and a certain amount of stock taken by the citizens, Mr. Ames will undertake to secure the necessary capital to carry the scheme through.

Niagara Falls, N. Y.—Officials of the Niagara Falls Power Company say that they have had more applications and inquiries for power in the last month which really look like business than they have ever had in an equal period. Many Eastern manufacturers and others are writing to them and visiting them in relation to power. The company has closed some large contracts recently and expects to do plenty of business. The Carter-Crume Carbide Works with triple its present plant and another concern that will use a large amount of power will employ 400 hands. Its factory will be situated near Echota. Other large concerns are negotiating for power.

North Tonawanda, N. Y.—A new power house is to be built here for converting and supplying Niagara Falls power to manufacturers and to the Buffalo & Lockport Railway Company. The machines which will be installed when the building is finished will be principally transformers and converters similar to the

big machines now in operation in the Lockport power house of the Buffalo & Lockport Railway.

St. Cathaiines, Can.—The formal opening of the Cataract Power Company's plant at De Cew's Falls took place on the 12th inst. The works were inspected by about 160 guests, including members of Parliament, editors, engineers, etc., from Hamilton, Toronto and elsewhere. The water for the power house at De Cew's Falls is taken from the Lake Erie level of the Welland Canal at Allanburg. It is brought through the company's private canal four and a half miles to the top of the mountain, where it is stored in three immense reservoirs, covering about 35 acres. The water is conveyed from the reservoirs to the power house at the foot of the hill by a huge steel pipe, eight feet six inches in diameter and 750 feet long. The water falls 270 feet into the power house, where the big steel pipe is divided into four branches. To two of these branches horizontal turbines of 2,000 horse power each are attached. The turbines are connected with 1,500 horse power electric generators by leather links instead of a belt. The total capacity now is 3,000 horse power, but connections are left ready so that the capacity can be doubled at any time.

COMPANY MATTERS.

Boston, Mass.—The Massachusetts Electric Freight Company, through James Means, A. M. Howe and Andrew Fiske, of this city, has filed a petition for incorporation by the incoming Legislature, and with authority to make contracts with existing electric lines to carry freight.

Charleston, W. Va.—The New York Wharf & Warehouse Company of Brooklyn, N. Y., has secured a charter here, empowering it to construct and operate elevated railways, motor-cars, docks, wharves, warehouses, piers, manufacture and supply gas and electricity, operate lines of telephone and telegraph, maintain ferries between New York City and Yonkers and points in New Jersey, etc. Capital subscribed, $50,000, with the privilege of increasing the same to $500,000 in all. The shares are $100 each, and are held by Stephen M. Hoyt, William W. Fish, John McDowell, Charles H. Friganza and William Meserole of Brooklyn, N. Y.

New York.—H. B. Coho & Co., dealers in electrical supplies, formerly at No. 30 Cortlandt street, called a meeting of their creditors at No. 143 Liberty street on the 18th inst. About 75 per cent. of the creditors attended. The liabilities are $60,000, and assets estimated at $40,000. A committee of five creditors was appointed to wind up their affairs, collect the outstanding accounts and divide the proceeds pro rata among the creditors. The committee consists of representatives of the Eddy Manufacturing Co., Oswego Boiler Works, Marietta Manufacturing Co., the City Bank of Hartford and the Harrisburg Foundry & Machine Works. The business was started in 1884 by Herbert B. Coho and the "Co" was Geo. C. Hoffman. Mr. Coho has obtained an injunction restraining Mr. Hoffman from disposing of the property of the firm, collecting any money and compromising any claim due the firm.

PERSONAL AND MISCELLANEA.

The substitution of electricity for horse traction on one of the large canals in England is viewed with much interest, for there can be no doubt that the full utility of these inland waterways is not realized, largely owing to the cost of traction and the increased toll consequent on their inability to compete in this respect with railways. There are 4,000 miles of canals in England, and but an indifferent attempt has been made to supersede horses by steam propeller boats, as in Scotland.

A curious state of things was observed in investigating the electrolysis of water pipes in Dayton, O., in which it was found that stones and pebbles near the pipes in some cases seem to have been electroplated with the metal of the pipe, a circumstance which one of the experts believes has never been observed before.

RECENT COMPANY ELECTIONS.

Bristol & Plainville Tramway Company, Bristol, Conn.—President, C. S. Treadway; vice-president, N. E. Pierce; secretary, H. J. Muzzy; treasurer, M. L. Tiffany; directors: M. L. Peck, O. F. Strunz, W. S. Ingraham, W. A. Ingraham, N. E. Pierce, E. N. Pierce and J. H. Sessions.

Emmitsburg Railroad Company, Emmitsburg, Md.—President, William A. Hines; vice-president, Rev. William L. O'Hara, president of Mt. St. Mary's College.

Merchantville Light, Heat & Power Company, Merchantville, N. J.—Directors: F. A. Downes, F. J. Burr, W. N. MacCallum, E. S. Hall, George W. Algor, E. T. W. MacCallum, George P. Williams, F. C. Robbins and William Griffiths.

Peoria General Electric Company, Peoria, Ill.—President, Peter Coffey; vice-president, Philip Zell; treasurer, Martin Kingman; secretary, Matthew Farrelly; directors: Leslie Robison, Matthew Farrelly, Julius Schwabacher and the officers.

United States Electric Lighting Company, Washington, D. C. Directors: A. A. Thomas, Stilson Hutchins, Seymour W. Tullock, Walter Hieston, W. A. Mearns, James L. Norris, George W. Pearson, Charles C. Duncannon, Clarence F. Norment, John Cammack, S. J. Butterfield, W. H. Slater and Charles Werner; all re-elected except W. A. Mearns and Walter Hieston, who take the places of Geo. W. Gray and Dr. Thomas O. Hills. James L. Norris has been elected president of the company.

Urbana Electric Light & Power Company, Urbana, O.—President, Frank Chance; vice-president, Charles H. Ganson; secretary and treasurer, John C. Powers; superintendent, Frank E. Valentine; directors: the officers and George W. Hitt.

COMMERCIAL PARAGRAPHS.

Alternating Currents and Transformers.

The Lakon Company of Elkhart, Ind., has published a booklet entitled "The Lakon—A Book for the Busy Man on Alternating Currents and Transformers." A unique

LAKON COMPANY'S $7\frac{1}{2}$ K. W. TRANSFORMER.

feature of this booklet is a description of the principles of alternating currents, with special reference to their application to transformers. The book describes the new line of transformers which this company has recently placed upon the market. These transformers are of the oil type, and although they may be used without oil the company strongly advise the use of oil in all sizes, as the oil aids in the dissipation of heat and prevents deterioration of insulation due to high temperatures. A pair of very strong and simple all porcelain fuse boxes are furnished with each transformer.

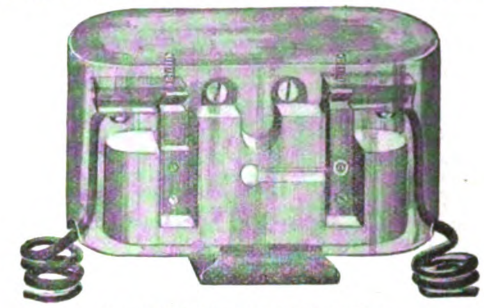
The method of hanging is extremely simple. It is with extreme ease and facility that the light Lakon hanging hook can be held in position and lag screws and bolts put in place by one man, and when the transformer is hoisted to be hung upon the hook it can be swung into position and quickly and easily lowered into the hanging hook.

A transformer having a high full load efficiency will not necessarily have a high all-day efficiency, and it is the all-day efficiency which is important. In order to secure a high all-day efficiency the transformers have been designed for a very low core loss, and good regulation is secured by a symmetrical arrangement of the windings and a liberal use of copper. The primary and secondary cables are brought out on opposite sides of the case through heavy porcelain bushings and are firmly cemented into the porcelains, so that there will be no chafing or wearing away of the insulation where the cables come through the case.

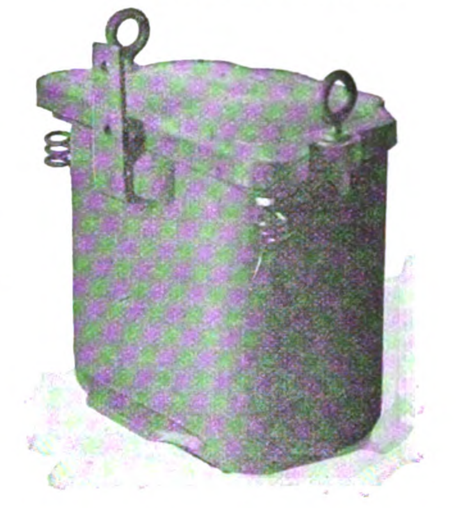
The aging of iron has been investigated by this company and they will replace within two years any transformers that will show any marked change in efficiency due to aging of iron.

In the Lakon transformer the coils are so arranged that a very large surface of copper is exposed to the oil so that the temperature is kept down to a very low figure.

The transformers are designed to withstand a very high break-down test between primary and secondary and between primary and core. While a very high insulation between primary and secondary is a safeguard against burn-outs from lightning, a transformer cannot be made in which the insulation in itself is enough to withstand the extremely high potential of a lightning discharge, and the company advocates a more general use of lightning arresters. Metallic ground shields will be placed in transformers when specified, but they do not advise the use of them on account of the increased danger of a puncture in

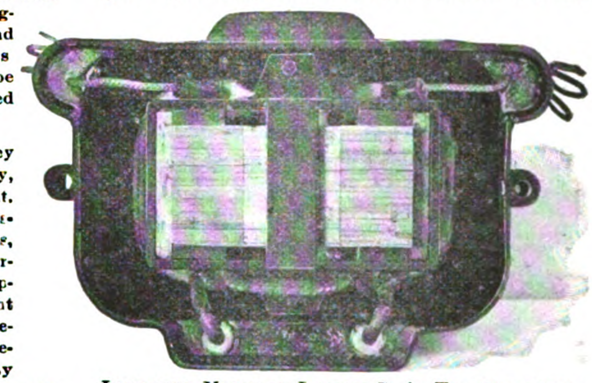


LAKON COMPANY'S FUSE BOX.



REAR OF CASE SHOWING LAKON COMPANY'S HANGING DEVICE.

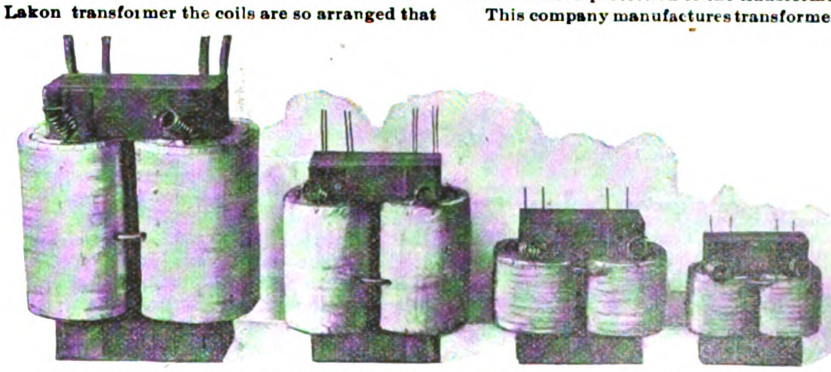
the insulation due to a lightning discharge. The ground shield being connected to earth affords a free path for lightning, and they believe that the transformer is more



INTERIOR VIEW OF LAKON CO.'S TRANSFORMER.

liable to be burned out by lightning when ground shields are attached. The ground shield will prevent the lightning discharge from appearing on the secondary circuit, but it is not a protection to the transformer.

This company manufactures transformers for alternating current arc lamps, step-up and step-down transformers, and transformers for special purposes, such as electrocautery, electric welding or testing purposes.



LAKON COMPANY'S $7\frac{1}{2}$ K. W., 4 K. W., $1\frac{1}{2}$ K. W. AND $\frac{1}{2}$ K. W. TRANSFORMERS.

INCORPORATIONS.

The Cincinnati, Lawrenceburg & Aurora Electric Street Railway Company, Aurora, Ind. Capital stock, $10,000.

The Gregory Electric Company, Chicago, Ill. Capital stock, $100 000. Incorporators: C. A. Gregory, G. A. Fargher and G. K. Wadsworth.

The Rocky Ford Electric Company, Pueblo, Col.—to build and operate a general electric plant in Rocky Ford. Capital stock, $15,000 Incorporators and directors: J. B. Downey, F. A. Kittler and F. L. Cuddeback.

The American Engineering Company, Camden, N. J.—to construct and equip railroads or railways, electric light, gas and other plants. Capital stock, $100,000; amount paid in, $1,000. Incorporators: Samuel B. Vrooman, Nathan Cox and John B. McAfee of Philadelphia, Pa.; John H. Tunstall of Camden.

The Electric Motor & Equipment Company, Newark, N. J.—to deal in, operate, manufacture and repair electric motors and electric machinery. Capital stock, $100,000. Incorporators: Augustus J. Miller, Joseph G. Ward, Jr., and Frederick G. Agens, Jr., of Newark.

The Newtown Alliance Company of New York City—to manufacture electrical supplies. Capital stock, $25 000. Directors: James A. Stiles, Hempstead; David E. Drake and Louis Beck, Newark, N. J.; Charles L. Eidlitz and Benjamin F. Hamilton, New York City.

The Fort George Extension Railway Company, New York City—to build and operate an electrical surface road from 172d to 185th street on Eleventh avenue, New York. Capital stock, $10,000. directors: M. G. Starrett, W. P. Plummer, John Lambdon, Andrew Loughlin, D. W. Patterson and Harry Hartwell of New York City, John Kerr and Charles E. Corby of Brooklyn, and H. A. Himely of Far Rockaway.

The Holbrook Land & Water Company, Provo, Utah—to acquire, cultivate and dispose of lands, construct and acquire reservoirs for impounding water, canals, aqueducts, conduits, flumes, pipes, ditches, dams and other things necessary to impound, control and distribute waters for irrigation, domestic and power purposes, including the erection and maintenance of electrical transmission lines and systems. Capital stock, $300,000. Incorporators and directors: Lafayette Holbrook (president), Emily A. Holbrook, B. S. Hinkley (secretary and treasurer), all of Provo; James A. Melville (vice-president), and Joseph E. Ray, of Fillmore.

ELECTRICAL PATENT RECORD.

Letters Patent Issued November 15, 1898.

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

614,082. Intermittent Electric Surface Conductor. Frank Burger, Fort Wayne, Ind., assignor of three-fourths to Henry M. Williams, same place. Filed July 23, 1897.

614,124. Electric Switch Mechanism for Electric Railways. John M. Murphy, Torrington, Conn., assignor of two-thirds to David F. Halstead, New York City, and William M. Keepers, Newark, N. J. Filed Sept. 3, 1897.

614,133. Switch-shifting Mechanism for Electric Cars. Jeremiah P. W. Roach, Concord, N. H. Filed Feb. 1, 1898.

614,161. Electric-Car Truck. Edward Oliff, Newark, N. J. Filed Aug. 24, 1898.

614,208. Trolley. Francis A. Le Court, Rockport, Mass. Filed June 17, 1898.

614,321. Trolley-Controller. John Dolan, Dayton, Ohio. Filed April 23, 1898.

614,412. Electric Switch-Operating Mechanism for Railways. Louis E. Walkins, Springfield, Mass., assignor of one-half to George M. Jewett, Glenville, Md. Filed Sept. 7, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

614,318. Portable Electric Lamp. Owen T. Bugg, Jr., New York City. Filed March 15, 1898.

ELECTRICAL MACHINERY AND APPARATUS.

614,076. Alternating-Current Motor and Mode of Operating Same. Charles S. Bradley, Avon, N. Y., assignor to the General Electric Company of New York. Filed June 22, 1895.

614,225. Electric Meter. Ludwig Gutmann, Peoria, Ill. Filed Dec. 4, 1897.

614,573. Arrangement for Exciting Magnets of Dynamo-Machines. Max Deri, Vienna, Austria-Hungary. Filed July 27, 1898.

614,394. Starting Resistance for Alternating-Current Motors. Ernst L. K. F. Kahlenberg, Berlin, Germany, assignor to the Siemens & Halske Electric Company of America, Chicago, Ill. Filed Dec. 30, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

614,207. Telephone-Exchange System. William E. M. Jackson, Chicago, Ill. Filed Jan. 14, 1896.

BATTERIES.

614,228. Method of Charging Secondary Batteries. Cyprien O. Mailloux, New York City. Filed April 24, 1891.

614,339. Electric Accumulator. Frederico Pescetto, Turin, Italy. Filed Dec. 24, 1897.

MISCELLANEOUS.

614,190. Magnetic Chuck. Oakley S. Walker, Worcester, Mass. Filed March 11, 1897.

614,240. Traction-Dynamometer. Edward A. Uehling, Newark, N. J. Filed Oct. 15, 1897.

614,270. Insulated Supporter for Electric or Other Wires. Charles K. King and George A. Mead, Mansfield, Ohio; said Mead assignor to the Ohio Brass Company of Ohio. Filed June 29, 1898.

614,288. Thermostat. Edward Cary, New York City, assignor to Alice Gilbert and Charity Cary, same place. Filed Sept. 16, 1897.

614,401. Signaling Apparatus. Morris Martin, Malden, Mass., assignor, by mesne assignments, to F. Benedict Herzog, New York City. Filed Sept. 28, 1885.

DESIGN.

29,682. Drop for Use in Electrical Warp Stop-Motions. William H. Baker, Central Falls, R. I., and Frederic E. Kip, Montclair, N. J. Filed Oct. 25, 1898.

TELEPHONE AND TELEGRAPH.

Chief Hale of the Kansas City, Mo., Fire Department has invented an electric fire alarm which is claimed to be superior to the systems now in use. As described in the Kansas City *Journal*, "the apparatus is a combination of the telephone and the graphophone, so arranged as to work automatically. The idea is to place thermostats at frequent intervals about the various rooms of a building and connect them by wires to a graphophone which is connected with the business telephone of the house. The wires from all the thermostats on any one floor run to a reproducer which is poised above a wax cylinder in which record has been made. The thermostats on the next floor are connected with a reproducer poised over another line. And so on for all the floors of the building. The thermostats are so sensitive that a very little increase in the heat in the room, such as would be made by a fire in any portion of it, breaks the electric circuit. This lets the reproducer for that particular floor drop upon its proper wax cylinder, and the graphophone begins repeating its alarm into a telephone transmitter connected with the central office which notifies the fire department."

An ordinance has been introduced in the city council of Columbus, O., granting a 25-year franchise to the Ohio Telephone Company to operate in that city. According to the provisions of the ordinance the company is to allow the use of its poles for the police and fire-alarm telephone systems, furnish 75 telephones free of cost to the city and pay an annual rental of 1 per cent. on the gross receipts of the company on the first $100,000, 2 per cent. on the gross receipts over $150,000 and 3 per cent. on the gross receipts over $200,000. The rentals fixed by the ordinance are $3 a month for residences, $4 a month for business houses, unless the company places its lines in a conduit, when the right is reserved to add to the price not to exceed $1 per month The percentage is to be assessed on the gross receipts as made out in an affidavit by the president or superintendent of the company on or before January 15 of each year and paid into the general expense fund.

The Automatic Telephone Company of New Bedford has been organized in New Bedford, under the laws of Massachusetts. The capital stock is $100,000, par value of shares $50. Thirty prominent business men of New Bedford are the incorporators, who have elected the following officers and directors: President, John W. Macomber; vice-president, F. T. Akin; treasurer, Frederick Taber; clerk, Arthur R. Perry; directors, the above and B. F. Brownell, Lot B. Bates, Frank R. Kirby, Jos. Poisson and J. L. Gillingham. The company proposes to construct a first-class underground telephone system, with private metallic circuits for each subscriber, and long distance instruments, as soon as 500 subscribers have been obtained; 400 have already been secured.

A Boston exchange states that the Erie Company has recently introduced in Texas a new class of service that is known as the " one way five party service." That is, one may have a telephone in his residence from which he can communicate with all the subscribers connected with his exchange at the rate of $12 per annum, but no one is allowed to call this subscriber and his name is not listed on the books. This same class of service is furnished for business purposes at $15 per annum. Other improvements in the service have been made recently, and President Glidden, who has just completed a tour of inspection on the Pacific Coast and in the Southwest, has arranged for a further material betterment of the system in various directions.

A dispatch from Embreville, Tenn., to the Knoxville *Journal* states that the directors of the Nolachucky Telephone & Electric Company recently declared a dividend of five per cent., payable December 1. This company started three years ago with a capital of $2,500 and a line fifteen miles long. It now has eighty miles of main line. Both towns of Washington county, Jonesboro and Johnson City, are thoroughly gridironed with its wires, and all the progressive men in the county are on the list of subscribers. The company has recently completed a metallic circuit to the Greene county line, which will enable it to give all subscribers through connection to Knoxville via the Greeneville, Morristown and People's telephone lines.

The Iowa Telephone Company purchased a switchboard which had been on exhibition at the Trans-Mississippi Exposition at Omaha and will install it at the Sioux City, Ia., exchange. The cost of the board was $20,000. It is known as a relay multiple board, common battery system, with electric lamp signal, and by means of the multiple feature one operator receives a call and completes the connection without having to transfer it to a second operator, thus avoiding mistakes and misconnections.

The Electrical Committee of Councils at Philadelphia on the 18th inst. took up for consideration an ordinance amending the ordinance granting privileges to the Standard Telephone & Telegraph Company. After a brief discussion, developing some opposition to the amended clauses, the matter was laid over for future consideration. Mr. Wetter, one of the firm that built the conduit for the company, who was present, said that 108 lineal miles of conduit had been laid; that the company had a well equipped factory in the city for the construction of telephonic apparatus and that the enterprise was backed by Philadelphia capital.

A Paris dispatch to the N. Y. *Morning Telegraph* states that the French Government has solved the much vexed telephone problem and will at once introduce in Paris and all the larger cities of the country a new system of telephone service. The plan provides for the erection of a large central station and a number of substations in different parts of the city. Waiting rooms will be provided for the accommodation of the senders and receivers of messages. The latter will be delivered from substations or from the central station at a cost of five cents. It is believed that under the new system the public will be better accommodated than ever before.

E. C. Spalding of Atlanta has been appointed by Judge Emory Speer of the U. S. Court temporary receiver of the Augusta Telephone & Electric Company, in the suit of Thomas & Post of New York. The company is operating the largest telephone plant in Augusta and uses the Strowger system. The Atlanta *Constitution* says that Mr. Spalding can command all the money needed to put the Augusta company on a sound basis and carry out plans for the extension of the service.

A final settlement has been effected between the U. S. Post Office Department and the Western Union Telegraph Company. The amount found due that company on account of the rates fixed by Postmaster General Wanamaker and the rates claimed by the company aggregated $260,000, which has been paid.

All negotiations have been closed between the Oregon Telephone Company and the Santiam Telephone Company for the purchase of the latter's line which connects Salem with Turner, Aumsville, Sublimity and Stayton, Ore. The former company is now pushing forward at a rapid rate, and expects to have a 'phone in every city in Oregon before many months pass.

The telephone line from Tishomingo has been completed to Silo in the Indian Territory. Telephone connection is now complete between Tishomingo, Silo, Oakland, Emmet, Ardmore and other small places in the Chickasaw nation as well as with Durant and Denison, Texas.

A few nights ago an electric light wire at Jackson, Tenn., fell across the telegraph wires of the Nashville, Chattanooga & St. Louis road, burning out the switchboards and setting fire to the stations seventy miles up the line and sixty miles down the line.

The work of constructing a telephone line on the west shore of Lake Champlain, from Whitehall to Plattsburg, has been completed. The line also extends to Upper Jay, Ausable Forks, Keeseville, Elizabethtown, Keene and Westport.

Duluth will soon have telephonic connections with Cloquet and Carlton. The Duluth Telephone Company has obtained the privilege of running its line through the latter place. The company has a large force of men at work and it is expected that the line will be completed in a few weeks.

The new telephone line between Opelika, Ala., and Lafayette has been completed, and Opelika is now the center of a network of wires extending in every direction except to Birmingham.

W. F. Vandiver, F. M. Billing and others have been granted a franchise for the establishment and maintenance of a telephone system in Montgomery, Ala.

The Carolina Mutual Telephone Company's plant at Charleston, S. C., has been purchased by the Gordon Telephone Company.

The Board of Education of Colorado Springs, Col., are considering the question of putting in telephones in the school buildings.

New Companies Incorporated.

The Blissfield Telephone Company, Blissfield, Mich. Capital stock, $3,000.

The Inter State Telephone Company, Cleveland, O.—to construct and operate a telephone line from Cleveland to Cincinnati.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.

NOTES FOR INVESTORS.

Late quotations for copper are: Electrolytic, 12⅝@12¾c.; Lake, 13c.; casting, 12⅝@12¾c.

The Third Avenue Railroad Company, New York, has declared a quarterly dividend of $1.75, payable November 30. Books reopen December 1.

The Stilwell-Bierce & Smith-Vaile Company of Dayton, O., has declared a dividend of 2 per cent. on its preferred stock, payable December 1. Books reopen December 1.

At a special meeting of the stockholders of the Bossert Electric Construction Company, Utica, N. Y., on the 16th inst., it was decided to increase the capital stock from $16,000 to $75,000, to consist of 750 shares of $100 each.

Judge Grosscup of the U. S. Circuit Court at Chicago has declared null and void the ordinance giving a street franchise to the General Electric Railway Company on the ground that proper consents from property owners were never obtained.

In the U. S. Circuit Court at Chicago last week Judge Showalter entered a decree ordering the sale of the Metropolitan West Side Elevated Railroad, the upset price to be $6,000,000. It is expected that the sale will take place early in January next.

It is stated in a dispatch that the Milwaukee Street Railway Company, upon a guarantee that competition in the street railway business will be shut out, has agreed to pay, in addition to its taxes, an annual sum which will amount to $1,000,000 in ten years.

At the annual meeting of the Third Avenue Railroad Company, New York, on Wednesday last, Samuel Riker was chosen a director to succeed R. W. Tailer, resigned, and John Beaver, treasurer, was appointed secretary temporarily in place of Alfred Lazarus, whose death occurred on the Tuesday preceding the meeting.

The Newport News and Old Point Railway & Electric Company of Newport News, Va., on the 16th inst. filed in the Elizabeth City County Court a mortgage deed, securing $900,000 of bonds issued by the railway company. The bonds were sold to Alexander Brown of Baltimore and the Maryland Trust Company.

The directors of the Newport & Fall River (Mass.) Street Railway Company have declared a semi-annual dividend of 3 per cent., payable January 1 to stock of record December 15. This is the first dividend declared by the company. The road has been in operation since June 19 and up to November 1 earned net $20,897.

Suit has been entered at Pittsburg, Pa., by the Pittsburg & Birmingham Traction Company against H. Sellers McKee, Murray A. Verner and others, who, as charged in the bill, "did by various contrivances, schemes and acts in 1891, 1892, 1893 and 1894 cheat and defraud the Traction Company out of a sum exceeding $1,000,000."

The reorganization committee of the Staten Island, N. Y., Rapid Transit first mortgage 6 per cent. bonds, due January 1, 1913, J. W. Davis, chairman, announces that a large proportion of the bonds have already been deposited with the Guaranty Trust Company of New York, and that the time for receiving additional deposits has been limited to December 5.

The amalgamation of the Kings County Electric Light & Power Company and the Brooklyn Edison Electric Illuminating Company went into effect on the 14th. The Edison Company will continue its organization as heretofore, but the electric light business will now be directed by the managers of the Kings County Company, which represents a union of the Citizens, Municipal, Edison and Kings County companies.

A report comes from St. Louis that consolidation of five of the largest street railway corporations in that city, of which the Lindell Railway and the Missouri Railroad are the principal lines involved, is now under consideration and will be arranged by January 1. The present capital stock of the five roads is $6,400,000 and they are bonded for $3,700,000. The consolidated lines will be incorporated for $10,000,000.

The negotiations looking to the consolidation of the City Passenger Railway Company and the Consolidated Street Railway Company, of Baltimore, will, it is thought, eventually culminate in the purchase of the former by the latter. Should this come to pass about $12,000,000 would probably be involved in the deal and $1,000,000 or more would be expended in immediate improvements, including the change of some cable lines to electricity.

The annual returns of the Connecticut street railroad companies for the past year, now in the hands of the State officials, show that the most prosperous roads, judging by the dividends paid, are the Hartford Street, 3½ per cent.; Danbury & Bethel, 4 per cent.; Fair Haven & Westville, 6 per cent.; New London Street, 5 per cent.; Norwalk Street, 4½ per cent.; Waterbury Traction, 3 per cent., and the Winchester Avenue, which paid in dividends last year a sum equal to over 8 per cent. on its stock.

A press dispatch states that a consolidation of the electric light companies of Baltimore has been virtually completed. The plan is to merge the Brush Electric Company, the Edison Illuminating Company and the Northern Electric Company into a new company, which would have a capital stock of $5,000,000 and bonds of $4,000,000. The Brush Company is controlled by the Westinghouse Company of Pittsburg, and the Edison Company is owned by the General Electric Company. The Northern Electric Company is composed of Baltimore capitalists.

Under the decision of Judge Coxe obtained last month against the General Electric Company, sustaining the patent of L. B. Marks on an arc lamp infringed by the General Electric Company, the Marks Enclosed Arc Light Company has compelled the removal of a number of General Electric lamps installed in New York. Notice has also been served on B. Altman & Co., the largest users of General Electric lamps in New York, to remove the lamps. The General Electric Company is alleged to have sold 40,000 of these lamps, all of which infringe the Marks patent.

The Boston "Advertiser" says: "The result of the over-bonding of many Connecticut electric roads has become apparent in their reports. Out of 27 only 10 have been able to pay dividends so far this year. These 27 roads have during the past nine months issued approximately $11,311,800 of bonds as compared with $9,092,800 last year, and yet their gross earnings show but a slight increase, while the net show an actual decrease. The time is not so far distant when the first flush of the boom in trolley roads will have worn off. Thus it is likely that a general reorganization throughout the country, similar to that in steam roads will begin. Naturally there are many electric lines to which these strictures do not apply, but the majority are certainly open to them."

Henry Clews in a letter published in the New York "World" speaks optimistically of the business outlook, and, referring to the stimulating effect on trade of the approaching Paris Exposition, says: "The most marvellous ingenuity we shall see there displayed will undoubtedly be in the various uses of electricity. This wonderful agent is coming more and more completely under human control every day and new uses are constantly developed. It is bound to play a very important part in the future and will almost revolutionize many industries, and instead of the present concentration into huge manufacturing establishments, the tendency will be toward distribution. We shall soon see it installed in the humble apartment of the lowliest workingman, and many tasks may then be finished amid the peaceful surroundings of his home, and who can gainsay the great moral benefit ensuing."

ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4081 Cortlandt.

SUBSCRIPTION RATES:

UNITED STATES, ...	$2.50
IN CLUBS OF FIVE OR MORE, ...	2.00
FOREIGN COUNTRIES, ...	4.50
SINGLE COPIES, ...	10 cents

Remit by Express, Money Order, Draft, Post Office Order or Registered Letter.

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

The Recent Snow Storm and the Underground Trolley.

The unusually heavy fall of snow which visited this region on the 26th and 27th inst. succeeded in throwing out of service almost without exception every conduit electric railway system operating in New York City. Trouble was experienced on all the electric lines of the Metropolitan Street Railway Company which prevented the running of cars for periods ranging from a few hours to twenty-four. For some reason the line apparently the least affected was the Madison avenue line, whereas the Lenox avenue line had to stop operating on the evening of the 26th and traffic was not resumed until the following evening. The other electrically operated lines, namely those along Second, Sixth and Amsterdam avenues, fared about as badly as that along Lenox avenue. The storm, leaving a fall of 12 inches of snow on the level in the city, was probably without exception the most trying that has visited this neighborhood since the adoption of conduit electric traction by the Metropolitan Street Railway Company, and what undoubtedly added to the difficulty in keeping the lines in operation was the fact that so severe a snow storm was scarcely looked for so early in the season and consequently caught the street railway companies unawares.

The stalling of the several underground trolley systems is explained by President Vreeland of the Metropolitan Company as follows :

"The snow of Saturday last was of a particularly wet kind, and melted quickly when it touched the rails of the street car lines. Ice then formed. In the case of the electric lines the presence of ice on the tracks prevented the wheels of the cars coming in contact with the iron rails, thus preventing the establishment of a circuit. Having no electrical power the cars, as a matter of course, could not move."

For that matter, however, this trouble was not confined solely to the conduit systems, but was also experienced in New Jersey, Long Island, and in fact in all the surrounding country, on the overhead trolley systems as well. The stalling of all the conduit systems owing to ice on the rails, which is a very serious matter in a city such as New York, brings up the question as to why the wheels and rails are relied on at all for completing the circuit. As the Metropolitan Street Railway Company is obliged to spend between $60,000 and $80,000 a mile when putting in its conduit systems it would seem as though for a few thousand more provision could be made for a complete metallic circuit without regard to the rails, and thus the chance of all the lines becoming inoperative in a snow storm would be to a great extent eliminated. In view of the fact that a storm such as the last means the loss of thousands of dollars to the company in fares, it would certainly seem as though it would be to its interest to provide a metallic circuit independent of the rails, to say nothing of the convenience of the public.

* * *

An Aerial Electric Railway.

So-called aerial railways, or those in which the cars are suspended from an overhead structure of some description, have been thought of and suggested from time to time as a means of overcoming some seemingly insurmountable difficulty, but none has as yet, at least to our knowledge, ever been constructed and put in actual operation. About a year ago a company was organized and plans drawn for an aerial railway over what is known as the Dyea trail, an extremely difficult portion of the route leading to the Klondike. In this case a heavy cable suspended on steel columns thirteen feet in height and 100 feet apart was to have served as the track, from which specially designed cars were to have been hung by means of steel bars. A second cable attached to the car itself was to have drawn it along by being wound upon a stationary motor located at an intermediate station on the line. The whole arrangement was apparently very crude, but this could probably be accounted for in the inaccessibility of the locality and in the desire on the part of the promoters to furnish some means of transportation which could be rapidly constructed. Recently, however, an electrically operated aerial railway has been suggested in Germany on which the work of construction has actually begun. Some method of transportation was found necessary connecting Elberfeld and Barmen, two cities situated about eight miles apart. Owing to local circumstances and to the topography of the country, apparently the only available route was over the bed of the river Wupper, but strenuous objections being raised against any obstruction of the river to navigation, the building of an aerial railway was determined upon. With this idea in view, inclined structural steel girders are being placed in either bank about sixty feet apart and will be held in position by means of longitudinal beams and trusses to which the rails will be attached. The structure will necessarily be quite high, as a number of bridges have to be passed over and a headway of sixteen feet is required between the bottom of the conveyance and all bridges. The cars will be hung from two rails, the axles of the wheels being supported on movable trunnions. Access to the cars, which will have a seating capacity of fifty,

will be had at given points by means of iron stairways leading up to platforms. The motive power will be electricity, which it is expected will propel the cars at a rate of speed of twenty-five miles an hour. There will be a double track along the whole length of the line, and every possible precaution will be taken in providing automatic devices with a view to eliminating all chance of danger should a car through any mishap become disabled. The work of construction is now progressing so rapidly that it is thought that by spring this novel railway will be in operation. Just why it was deemed advisable to operate this line as an aerial one instead of as an elevated road is hard to see for a structure such as had to be built to support the weight of a moving car hanging from it, especially when any swaying due to the action of a heavy wind is taken into account, would surely have been sufficiently strong and rigid to support the weight of a car moving along its top. Furthermore, had an elevated road been projected, built on the same principle as the aerial one, the cost would have been much less, as the structure would not need to be so high. The fact that an untried aerial railway was decided on, however, can probably be accounted for in the fact that as a rule foreigners do not take kindly to elevated roads such as we have in this country. In any case the opening of this aerial railway will be watched with interest and will undoubtedly be as unique in its way as the balloon railway in the Austrian Alps leading to the summit of the Hochstauffen Mountain at Bad-Reichenhall.

Excellent Showing of the Electrically Operated Machinery on the Brooklyn.

Some time ago we called attention to the advantages to be derived by equipping the new battleships of the Navy with electricity for operating not only the ammunition hoists and turrets, but all the other auxiliary machinery, such as winches, steering-gear, etc., as well. We now understand that this question of using electricity as the principal motive power in lieu of steam on the vessels of the Alabama class as well as on the Maine, Missouri and Ohio, for which contracts have but recently been let, is receiving careful consideration at the hands of the Board of Construction. This condition of affairs has been to a great extent brought about by the excellent detailed reports received by the Navy Department from the officers in charge of the Brooklyn, who were in a position to speak authoritatively of the comparative merits of the two forms of motive power. The Brooklyn is unquestionably the most thoroughly electrically equipped vessel now in commission in the United States Navy. Besides the ordinary electrical installations to be found on every modern war vessel at the present time, four 5-inch ammunition hoists, two 6-pounder ammunition hoists, eight 8-inch ammunition hoists and the forward and starboard turrets are all operated by electricity and were so operated during the naval engagements in Cuba. Lieut. W. R. Rush, of the Brooklyn, in an official report to the Navy Department as to the merits of electricity, says:

"In obedience to your orders requiring a report upon the relative efficiency of steam and electrically-controlled turrets, viewed in the light of the experience of July 3d in the naval fight with the Spanish fleet, I respectfully submit as follows:

"A board, of which I was senior member, appointed by your order of September 29, 1897, upon the same subject reported then: 'In suggesting modification in form or installation of turret guns or fittings, the board begs to reiterate its unqualified approval of electricity as the power for training turrets. To anyone who has trained turret guns upon a target by electricity, and who has afterward attempted to do it by any other means, the contrast is too striking ever to be forgotten. The electric motor and controller give perfect control and fineness of train to an ideal degree.'

"Now, after experience in handling turrets under fire, in a running fight of four hours, I fully endorse the report of the board given above. I would like to add in favor of electric turrets that the temperature of the closed handling room of the steam turrets was terrible in comparison. There was also the danger of death to everybody in the handling room from shell cutting a steam lead."

Lieutenant James G. Doyle of the same ship also submitted a lengthy report in which among other things he states:

"I have been closely associated with the turrets of this ship, both steam and electric, before and since the commissioning of the ship on December 1st, 1896, and have had the best of opportunities of observing their relative merits. I had charge of one of each kind during the battle with the Spanish fleet off Santiago on July 3d, the port waist (steam) and the starboard waist turret (electric). The facility with which the starboard turret guns (electric) were laid on the enemy's ships leaves no doubt in my mind that electricity is immeasurably superior to steam as the turning power for turrets, and I also believe this ship would be more efficient than she is now if electricity was adopted for the port and after turrets."

The above reports would seem to prove conclusively that electricity even under the most trying conditions is for many reasons better adapted for operating the turrets in a warship than is steam, and the fact that arrangements have about been made for operating the turrets of the Alabama, Illinois and Wisconsin by this form of motive power would seem an acknowledgment of the superiority of electricity over either steam or compressed air, but still leaves the question open as to whether all the auxiliaries should be operated likewise by the electric current. This important point, however, is covered by Admiral Sohley in his report to the Navy Department, in which the following statements appear:

"I would respectfully report that I am of opinion that the use of electricity as a motive power for all turrets, ammunition hoists, and all auxiliary machines on board ship not in the engine rooms is desirable and would increase efficiency.

"The use of steam for operating turrets makes necessary great lengths of piping and produces almost insupportable heat in the handling rooms; with electricity this is avoided and greater celerity is accomplished.

"In the battle of July 3d, the turrets controlled by electricity did better and quicker work and were not so hot as those functioned by steam.

"I would, therefore, heartily recommend electricity for these purposes."

The fact that no trouble of any sort arose through the use of electricity on the Brooklyn certainly speaks well for the electrically operated machinery, and proves beyond a doubt that the time has arrived when apparatus of this nature can be installed with confidence for almost every purpose on shipboard, and furthermore it would seem as though the excellent results obtained warrant its extensive use on the new ships of the United States Navy, to say nothing of the fact that for a Russian battleship now under construction in this country the use of electricity is contemplated for the manipulation of practically all the auxiliaries.

CABLE dispatches inform us that Spain has yielded all the United States Commissioners contended for, relinquishes Cuba and cedes Porto Rico, Guam and the Philippine Islands. This should stimulate the discoverers of wireless telegraphy to renewed zeal in the effort to perfect their inventions. We need some means of bringing our widespread possessions closer together, and if we can hold them without wires the whole country will rejoice and electricity be glorified.

Under the Searchlight.

Notes and Comments on Various Topics.

WHILE a certain manufacturer of acetylene gas generators in this city was showing a prospective customer, an Ohio lawyer, the working of a generator in the company's office the other day an explosion occurred. In lighting the jets of the machine one was forgotten and the gas escaped to the upper part of the room, where, after reaching a certain density, it exploded. The window pane was blown out into the street, and the lawyer in his haste to get out broke two panes of glass in a door with his cane. There was no other damage.

* * *

IN a recent damage suit brought against a local street railway company the defendants in support of their claim produced a trolley car—if not in court, at least as near as it could be gotten there, at the front door. Needless to say they won their case. If this tendency to produce mammoth mechanical evidence keeps on, the court rooms all over the country will have to be enlarged.

* * *

A CHICAGO inventor claims he has devised a new steam turbine which will be the means of propelling a railway train between New York and Chicago in sixteen hours, and may also be arranged to drive steamers at the rate of forty miles an hour. The Windy City is certainly fertile in producing startling inventions, which usually end in wind. Thus is the city well named.

His Rise.

(From the Cleveland Leader.)

There was a man who started out
  To elevate the human race,
To clear old heresies away
  And make the world a better place.
He delved in ancient, musty tomes,
  He often burned the midnight oil,
And labored that this busy world,
  Might be the better for his toil.

He wrote in verse and otherwise
  The lessons that he had to teach,
But no one bought his books nor would
  The people listen to him preach.
For years he sought to make the world
  A better and a fairer place—
To clear old ignorance away
  And elevate the human race.

At last, half starved and in despair,
  He put his books and pen away,
And lo! that which he strove to do
  He does with simple ease to-day:
He elevates the human race—
  Read on, and I will tell you how—
His rusty pen is idle, but
  He runs an elevator now.

* * *

THE arc lamp maker, says *Lightning*, London, is seldom without a tale of woe. The last I have been told is by an English maker who sent some arcs to North Italy, where they are supposed to know something about electricity. There came back a complaint that the lamps would not work satisfactorily like the German ones. On inquiry it came out that in the capital of Piedmont they are capable of ordering continuous-current lamps and putting them on an alternating-current circuit.

* * *

X-RAY parties, according to the New York *Sun*, are the latest fad in Brooklyn. Brooklynites nearly always amuse themselves seriously. Think of the trolley parties that they have! And those who know say that a trolley party is as devoid of smiles as a page in a newspaper run by women. But the X-ray party promises to oust the trolley party, at least during the winter, and it certainly is far more amusing. Few people think of science as side splitting, but they do say on the other side of the bridge

that the "X-rays are too funny for anything." These X-ray entertainments are given, of course, for charity; Brooklyn always amuses itself for the benefit of somebody or something. Such a thing as enjoyment for enjoyment's own sake is frowned down on from the Heights to the Hill.

Mind Pictures by Telephone.

"Did you ever notice that when an idea becomes fixed in the mind it is very difficult to change it, especially in the case of extremely sensitive and highly nervous persons?" asked a Brooklyn expert on nerves. "Not long ago I had a visit from a man who was afraid he was losing his reason because of a very simple persistence of a certain thought or idea which he could not shake off. The history of the case is one often found in cases of hypochondriasis developed from using the telephone. My patient for about a year's time had occasion to telephone every day to a trade customer in New York—Manhattan if you like.

"The New Yorker had a peculiar high tenor squeak to his voice, and somehow my friend got to picturing him as a little chap with a thin face. This habit grew day after day until the customer took a real shape and form in the mind of my patient, all based of course upon his voice. As he talked over the telephone there always was mentally pictured that little chap with the thin face and squeaky voice. Well, one day my patient called at the office of his New York customer, and as he walked into the place and saw a tall, fat man weighing nearly 300 pounds he could scarcely believe his eyes. When the fat man opened his mouth and talked, my patient says, the squeaky voice with which he was familiar sounded strange and unnatural. He told the owner of the absurd voice, in view of his size, about having pictured him as a little thin person, and there was a good laugh over the odd difference of the reality.

"But the next day when my friend used the telephone and the squeaky voice came to him, he had to struggle to get away from thinking of his fat patron as being little and thin. He talked the matter over with his wife and laughed about it, but soon there came a time when he forgot all about the actual existence of his customer, and the little thin-faced chap was again talking to him over the wire. Then it was that he came to me. He feared, he said, that his mind was giving way, because of the persistence of the odd picture of the thin man. I thought the case was easily disposed of, and told my friend to go to New York every day for a week and visit his fat customer. This he did, but every time he telephoned the squeaky voice would bring up the mental picture formed before he had set eyes on its owner.

"I was in despair and my patient was growing gray from worrying when I hit upon the happy expedient of placing a photograph of the fat man on the telephone, where the eye of the patient could rest upon it as he talked. The result was the disappearance forever of the thin chap. My patient, in looking at the picture of the owner of the squeaky voice, got his mind working upon the same lines that would have been followed had he met the fat man face to face the first time he heard his voice. These cases are common every day. We form queerly opposite pictures of men and women we hear over the telephone and never see, but in the great majority of instances the impression is a momentary one, and it is seldom that the mistake is ever forced upon us in the startling way described by the patient told of.

"The telephone, by the way, has produced very many queer cases of neurasthenia that remain unaccountable excepting on the hypothesis that the new habit brings them into existence. I have had very many patients who had to give up the use of the 'phone altogether where it had been used to a great extent before."—*New York Sun.*

SURFACE CONTACT ELECTRIC RAILWAYS.*

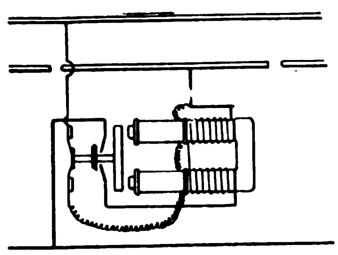
BY EDWARD H. JOHNSON.

In considering the problem of electrically operated surface railways, as in considering other problems, one inventor will from motives of expediency follow the general trend of the commercial evolution of his art, while another will look beyond and seek that solution which shall possess the element of permanency by virtue of being founded on correct theory.

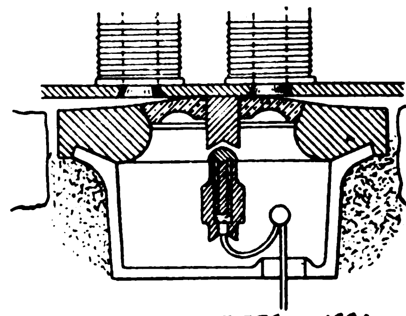
In no branch of modern electrical development has this divergence of inventive tendency been more marked than in that of electrical distribution for tram car service. The quick, cheap and effective overhead trolley afforded the "expediency" inventor a fruitful field. It was a rich harvest but it was a harvest of one season only. That season has passed. The phenomenal success of the electric tram car has in itself forced a "public opinion" in antagonism to the overhead supply system, hence the "expediency" inventor is again requisitioned, and following his nose with the instinct of his class says, "Take the trolley off the poles and string it in a cable slot." The fact that electricity and water are mortal foes and that a cable conduit is nothing more or less than an open street sewer has no weight with him since his client's margin of earnings is sufficiently great to permit not only of enormous expenditure for a construction that will secure drainage but also for paying the considerable cost of the excessive leakage inherent in the system.

It thus comes to pass that in metropolitan streets, where the traffic is of "bonanza" proportions, the problem of complying with a public demand may be and is being met by a brute force solution—a solution neither in consonance with scientific or commercial principles.

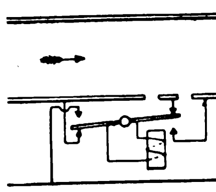
That such a solution of the problem is no solution at all for at least 99 per cent. of the tramways of our



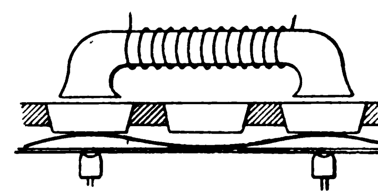
HOPKINSON—1882.



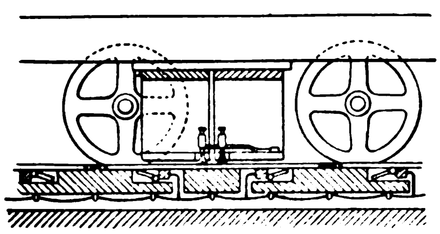
DIATTO—1894



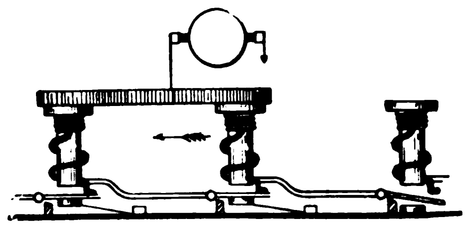
AYRTON-PERRY—1883



LINEFF—1888



POLLAK-BINSWANGER—1886



WYNNE—1887

American cities can easily be demonstrated by a comparison of their possible net earnings and the interest on the great investment demanded by it.

A further development of the art is therefore essential, and the brother inventor must now, perforce, be granted a hearing. Of him is required a solution of the problem which shall possess the element of permanency and which shall yet not demand an investment of prohibitive proportions. Immediately this inventor opens with his plan it is recognized as an old acquaintance, to whom not much attention has hitherto been paid and who has, in the whirl of expediency, been passed by with a gesture of impatience. Present necessity, however, now secures the recognition heretofore denied, and lo! it is discovered that not only is the plan a true solution but that it was as a matter of fact evolved fundamentally from the brain of the late and lamented Dr. Hopkinson 16 years ago, and it is safe to say that had it met with a tithe of the encouragement given to its overhead and open conduit brothers it would have been more speedily perfected, and neither the overhead nor the underground trolley would to day exist upon a single important street in either city or town.

An important factor effective in retarding the development of a sound system has been the unwillingness of the larger street railway syndicates to see any underground system a demonstrated success. Their overhead charter rights generally contain an obligation to substitute such a system on proof of its practicability, hence their determination to damn it in the eyes of the public and municipal authority. Even yet the corporations owning trolley franchises, while suffering their associates to develop the costly open conduit in the great and wealthy metropolis, having no fear of its being forced upon their less prosperous lines in minor cities, assume a position of determined hostility toward the cheaper and superior system, knowing full well that a single demonstration of its practicability in New York would promptly compel its general adoption in Philadelphia, Boston, Chicago and elsewhere.

* Read before the New York Electrical Society, Nov. 16, 1898.

THE PERMANENT SOLUTION.

The surface contact system, as its name implies, delivers the current to the moving car by virtue of contact between a bar or "skate" carried by the car and sectional conducting metals fixed in the surface of the roadway. The mere statement of the general conditions suggests as an essential requisite that the current shall be there for the car only, and not for the horse or other street user. This in turn implies the automatic charging of the surface contact points when needed by the car and their automatic discharge when the car has passed, by means of some force associated with the car itself, and since we are dealing with currents of many horsepower, it follows that the individual factors in this automatic operation must be absolutely reliable. In fact, the devices employed for the discharge of the current at least must be infallible. Nothing less will avail, since there can be no divided responsibility for accidents resulting from the use of such a system. A live section is as innocent looking as a dead one. It gives no notice to the street user and hence he is not charged with the responsibility of avoiding it. Under these circumstances the law would promptly condemn the system and compel its abandonment upon its first offence.

One deterring force of substantial weight which has operated to keep this system in the background is the common impression that these automatic factors could not be so designed as to at all times and under all circumstances possess this property of infallibility. Mr. Lundell and I have, however, held to the contrary, and after more than three years of almost continuous experimental work and practical demonstration are now able to challenge those who hold otherwise to place their finger upon a weakness in the system, which, if accidentally developed, would result in a dangerous electrification of the street.

The history of the origin and evolution of the surface contact idea is too varied and voluminous to be recounted in a brief paper, but I have prepared a few illustrations of the most ambitious efforts that have been made from Dr. Hopkinson down to our own, and will note briefly their salient features.

Dr. Hopkinson, the originator of the idea of surface contact, had only in mind the prevention of heavy leakage from a commercial point of view and not at all a matter of securing safety. Hence, his electrical connections were not designed and could not be considered for a moment as factors of safety. He simply overlooked the point of vital importance.

Ayrton & Perry 1883) simply diversified the electrical connections in many ways, but clearly with only the Hopkinson end in view. Their system was thus not superior to Hopkinson's and therefore no better adapted to secure safety.

Pollak & Binswanger (1886) were among the first to recognize the importance of safe-guarding the street, and they adopted the idea of operating switches in the street by electro-magnetism developed on the moving car. They have had many followers, among whom may be mentioned Wynne, 1887, Lineff, 1888, and Diato, 1894. The principle has, however, been found inadequate because unreliable at high speeds, a fact readily comprehended by those who understand the laws governing magnetism.

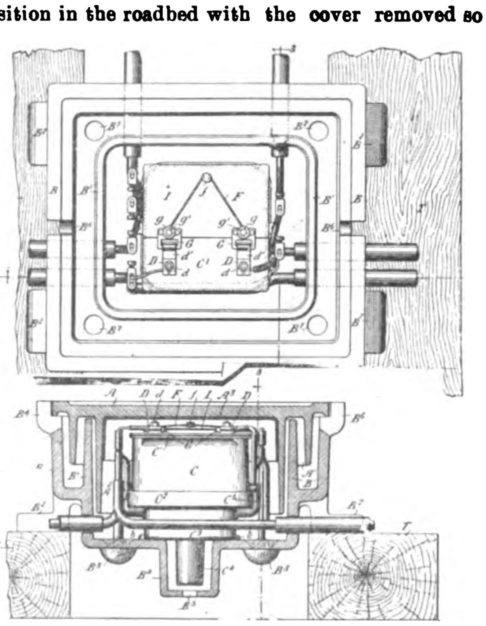
The latest candidate for honors in surface contact development is Prof. Sylvanus P. Thompson, who endeavors to combine the good points of the electro-magnetic switch system with the good elements of the pure "magnetic pick-up" system. The result is, however, not a happy one, as it involves the switch in complication, whereas, as every engineer and mechanic knows, an essential condition of infallibly operative mechanism is that it should be reduced to the last stage of simplicity, viz., a weight falling in free air.

As these multifarious steps in the evolution of the art have been taken, it has become more and more apparent that the positive acting electro-magnetic switch energized directly by an ample electric current, and possessing, as it does, the quintessence of mechanical and electrical strength and simplicity, will alone yield the positive and reliable results demanded in railway work. Moreover, as it has been found that a certain "time allowance" for the operation of the switches is essential for high-speed work, a duty requiring the switch to operate before it is reached by the contact shoe of the car, it is of course apparent that since the electro-magnetic switch is the sole device capable of responding at a distance, it alone is equal to such duty.

Mr. Lundell and I have from the outset recognized these severely exacting conditions, and have accordingly based our work entirely upon the electro-magnetic switch and sought to reduce it to the acme of simplicity and consequent reliability, as well as to evolve a system of circuit connections equal to every requirement of speed, direction, capacity, economy, reliability and safety. These results we not only claim to have achieved but in doing so to have produced a system so inexpensive as to justify its adoption wherever the overhead trolley is now financially successful.

THE SWITCH.

Fig. 1 is a plan view of the switch box in its position in the roadbed with the cover removed so



FIGS. 1 AND 2.

as to show the internal structure thereof (the line 2 2 being parallel with the roadway).

Fig. 2 is a sectional view taken on the line 2 2, Fig. 1.

Fig. 3 is a transverse sectional view taken on the line 3 3, Fig. 1.

Fig. 4 is a vertical sectional view taken through the body of the switch-enclosing box on the line 4 4 of Fig. 5, which latter figure is, in turn, a horizontal sectional view of the same switch-enclosing box taken upon the line 5 5 of Fig. 4.

Referring to the drawings in detail, and first to Figs. 1, 2 and 3, B represents a cast iron protecting box of rectangular form and provided with four legs, B^2 B^2 B^2, adapted to sustain the box in position between two ordinary cross ties, T T. This box is cast in one piece with an upwardly extending inner flange, B^1, running entirely around the interior of the box and adapted to form with the top or interior flange, B^4, a deep-seated groove, which we may call a mud groove.

A represents the cover of the box, which is also of cast iron and is provided with two downwardly extending flanges, A^1, A^2, the flange A^1 being adapted to extend a considerable distance into the mud groove, as will be seen on examination of Fig. 2.

The flange A^2 is somewhat longer than A^1 and extends to a point near the bottom of the box B, forming a sort of a dividing ball for the protection of the fuse block and terminals shown in the figures referred to.

The inner surface of the cover or lid A is lined with insulating material for the purpose of preventing any possibility of the continuance of an arc when the fuse, which is shown in Fig. 1, blows.

The switch enclosing box proper (see Figs. 4 and 5)

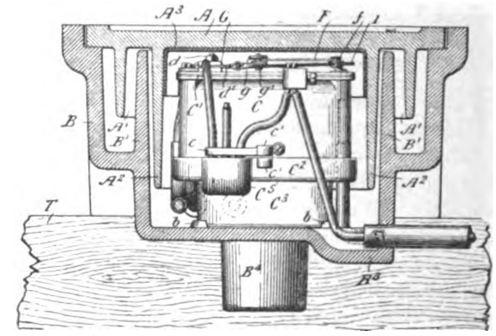


FIG. 3.

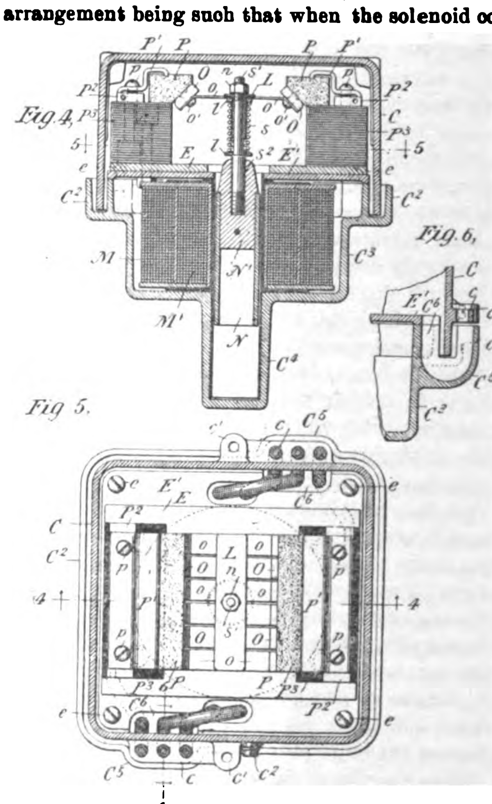
is composed of two cup-shaped parts, C and C^3, the lower part, C^3, being provided with an upper grooved extension, C^2, and a lower cylindrical extension, C^4, the arrangement being such that the lower edge of the upper portion, C, of the enclosing box will fit within the grooved portion, C^2. The lower portion, C^3, constitutes not only a part of the enclosing box but is also adapted to act mechanically as a part of the magnetic circuit of the electro-magnetic switch, E^1, being a cast or wrought iron plate with an opening in its center and held by small screws, e e e, to the upper face of the inner part of the grooved portion, C^2.

The lower part, C^3, of the enclosing box constitutes a chamber for the switch operating magnet, which is of solenoid form and is provided with two windings, M and M^1. the circuit connections for which will be described later.

N is a hollow solenoid core of soft iron secured to an insulating standard, N^1, which, in turn, is secured by a rod, S^2, to a series of yielding conducting arms, O O O, having secured to their outer ends a series of good metallic conductors, o o o, the whole arrangement being such that when the solenoid core



is in its lower position the metal contacts, o o, will rest on the upper surface of the insulating plate, E.

P^3 are blocks of insulating material, preferably slate, and P^2 are blocks of conducting material secured to the same.

P^1 are clamps for holding bevelled shape blocks of carbon, P P, in position, the arrangement being

such that when the solenoid core, N, is held in its upper position under the influence of an energizing current, the working current will pass from the conductor joining one of the carbon blocks P to and through the contacts 0 0 0, arms o o, and other contacts 0 0 0, to the remaining carbon block, P, and thence to the exposed sectional trolley conductor embedded in the roadbed in the manner well understood.

All of the parts of the switching mechanism are properly assembled in the workshop and placed in position in the enclosing switch box, C.

The cables leading to the switch boxes and to the ends of the magnet coils are bent downward to the side box C^5 as shown, and the cover C is placed thereon with its lower edge resting in the groove C^2, after which this groove is filled with paraffin or any preferred sealing material, thus assuring the fact that all of the operative parts of the switch will be protected at all times and ready for use when they arrive at their destination, where they may be placed in the outer box B^4 after the manner shown in Fig. 2, and the necessary connections made between the several conducting cables.

THE LEAK CIRCUIT.

This invention was the direct result of the frequent recurrence of a "live" section, consequent upon the leakage of current from the high potential button to the low potential or switch button, resulting in the maintenance of the magnetic switch in a closed position and a consequent "live" section after the car had passed, instead of allowing it to open and clearing the section as it should.

By interposing the track rail—i.e., the negative conductor—between these two buttons, electric connection between them was made absolutely impossible except through the motor, hence a switch magnet could only be energized by the motor current—which is, of course, interrupted by the passing of the car—and never by the leakage current, which, being independent of the car, remains as a source of evil. The importance of this provision against accidental electrification of the street, as well as its efficacy as a remedy, is acquiesced in by everyone who has thus far considered the subject.

Diagram B fully illustrates the manner in which the leakage currents are effectually guarded against. Upon examination of this diagram it will be noted that the magnet operating coils are contained in a circuit leading from the track rails to sectional rails placed outside of the same. As the current which energizes the magnets travels in a direction from the sectional rails to the track rails, it follows that any leakage from the sectional service conductors SC^1 SC^3 SC^5, etc., could never reach the outside sectional rails and cause a current to flow from said sectional rails to the track rails by way of the coils, all the leakage current necessarily being absorbed before it passes the negative track rails.

THE INTERCONNECTING FACTOR.

Experiments with the sectional rail system developed the imperative necessity for a "time allowance" for the operation of the switches before demanding current of the successive contact buttons or rails as the car progressed; this demand for time allowance is, of course, increased as the speed is increased. It is a fact that without such provision a car running 10 or 12 miles per hour would "run away" from the current—that is to say, the car would pass over a button so quickly that its switch would not have time to act, and consequently the motor current would not only fail but destructive sparking at the switch contacts would ensue. It is, of course, apparent that in the case of high speed trunk line roads this defect would be fatal. As to the efficiency of the means employed to give the requisite time allowance in a reliable and positive way, it needs only that the fact be stated that the current employed for actuating any given magnet is carried forward to and utilized in actuating the next succeeding one. If, therefore, the current employed is sufficient to energize the first, it must of necessity be sufficient for the next, thus insuring the operating simultaneously with the first and not at some indefinite period thereafter.

The connection, diagram A, will fully illustrate the manner of interconnections between the operating switch coils. For instance, the current will flow (see diagram) from sectional conductor SC^4 through wire W^4, through upper coil of magnet M^2, then by the interconnecting wire W^4 around the lower coil of magnet M^3 to track rail.

MISCELLANEOUS FACTORS.

In the progress of development ensuing from the continuous chain of experiments conducted by us, many deficiencies not otherwise discoverable were made manifest. Among these were the following:

1st. The fact that surface leakage from the high potential button to the track rails would suffice to keep the switch magnet energized if it were in the circuit between the main feeder and the high potential button; this led to a complete reconsideration of the electrical circuits. To remedy the difficulty, the switch magnet was finally placed in circuit between the motor and the track rails, instead of between the high potential button and the motor, thus insuring the absolute isolation of the switch magnet after the passage of the car. This was a new provision against the hurtful effects of leakage, as will be seen from this statement of its specific purpose and function, and quite different and apart from that provided for in the leak circuit.

2d. The fact that the interconnecting feature as originally worked out for street-railway work would not operate with equal efficiency in both directions, and therefore, though fairly satisfactory for street car work, would not at all fulfil the requirements of trunk line work; this led to its further consideration with consequent result of a circuit arrangement affording equally effective operation in either direction.

3d. The fact that when a motor attained a speed which caused its counter EMF. to approximate closely the direct EMF. of the line, the current passing would be so diminished in volume as to be insufficient to keep the switch magnets closed, thus producing an uncertain action with consequently dangerous fluctuations; this led to a consideration of ways and means to insure a fixed minimum current through the switch magnet, independent of and indifferent to the quantity of current taken by the motor. The means finally introduced to effect this object proved upon trial to be positive and reliable in operation; without this provision, heavy traffic lines cannot be operated by a sectional conductor system.

Diagram B, illustrating the leak circuit, will also clearly show the "by-path" feature. Upon examination of this diagram it will be noticed that the current for the motors flows from the positive main through the switch contacts to a sectional conductor and contact shoe through the motors and to the controller where it divides itself—one part of the current flowing by way of the negative contact shoe and sectional rail to and through the switch coils and finally to the rails on the return conductor; the other part flowing through a storage battery of low voltage (charging the same) to the car wheels and to the return conductor. It will thus be apparent that should the current through the motors diminish to any great extent, the current through the battery connection W^{11} will reverse and the battery will supply the additional current needed to safely work the electro-magnetic switches.

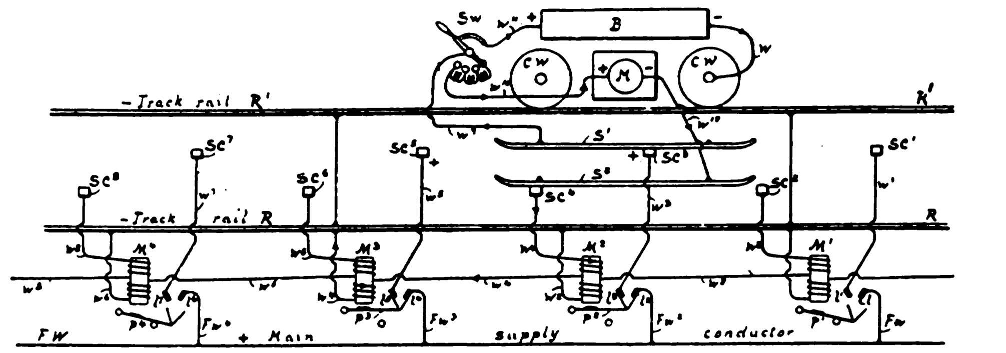


DIAGRAM A.

THE CROSSING PROTECTOR.

Among the many, and sometimes captious criticisms which our work has met with during the period of its development was one condemnatory of the use of a storage battery of material EMF. and current capacity and consequent cost and weight. We employed such a battery at the outset for the dual purpose of operating the magnetic switches and propelling the car over short distances, by the latter function obviating the necessity of electrically equipping crossings, switches, turn-outs and other situations otherwise involving not only expensive construction but great liability to interruptions consequent upon the possible short-circuiting of the conductors at such places. Although we presently gave ear to this criticism as one involving a prejudice not readily combated, we nevertheless adhere to the opinion that such combination of battery and direct supply will yet be found to be an exceptionally economical and practical system of street-car propulsion. However, having decided to concede the objection to be one deserving of our attention, we sought and found the means of dispensing with the battery and at the same time overcoming the liability to interruptions in the event of short circuits. The means discovered for accomplishing this may be expressed in the paradoxical statement that though a short circuit may occur, and the safety fuse be blown

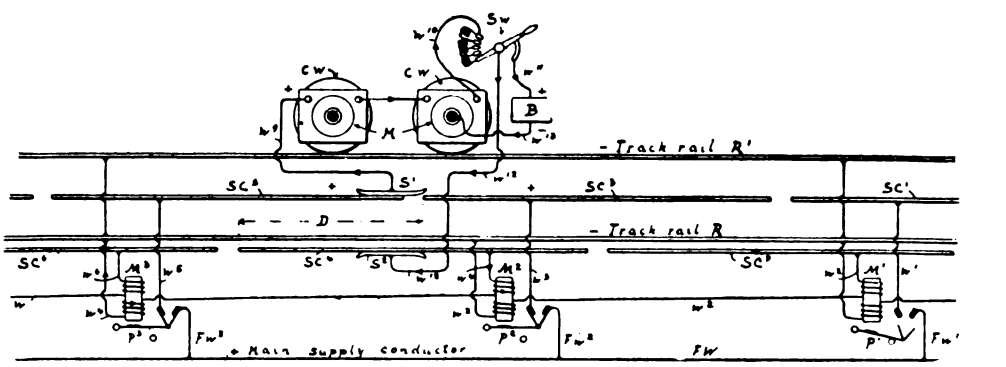

DIAGRAM B

the current will yet flow in sufficient quantity to propel the car off the impaired section and permit its continuing progress without so much as an actual stoppage.

Such a position is imperative in any surface contact system, since in any such system it is impossible to so differentiate the plane in which the positive and negative conductors lie as to render accidental short circuits improbable.

To illustrate this feature reference is made to diagram C where S^1 S^2 represent the trolley shoes which are connected to the motor on board of the car (not shown), R R^1 represent the tramrails of one line of rails and R^2R^2 corresponding lines of rails of a crossing tramway; SC^2, SC^4, etc., represent one line of sectional trolley conductors or contacts, and SC^3, SC^5, etc., represent the parallel line of sectional trolley conductors or contacts. B B represent two of the switch boxes, the circuit connections from the current feeder or main thereto and therefrom to the sectional trolley conductors being identically like those described in the previous diagrams.

F represents the fuse in the switch box, which is designed to "blow" for such current as may be deemed best, and X represents a resistance in a shunt or derived circuit about the binding-post to which the opposite ends of the fuses are connected, the arrangement being such that when any short circuit occurs between either of the trolley shoes, as S^1, one of the sectional trolley conductors SC^5 and one of the crossing lines of rails, as R^2, the fuse will be blown, but the circuit between the circuit connections in the switch box and that particular sectional trolley conductor or contact will not wholly be ruptured, and the sectional trolley conductor when connected through the circuit connection in the switch box will still carry sufficient current to move the car over the crossing to the next sectional trolley conductor in advance.

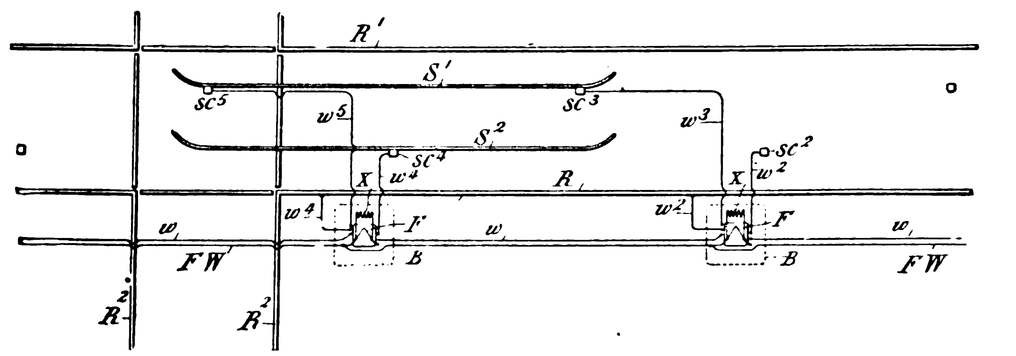

DIAGRAM C.

METALLIC CIRCUIT SYSTEM WITH REVERSAL OF LEAKAGE CURRENTS.

Considerable prejudice against the use of the tracks and the earth as a "return" conductor having been developed through the inefficient methods employed in the early days of the overhead trolley, and great stress being put upon the fact that in the open conduit system the track rails were not used as conductors, we thought it well to evolve, if possible, an alternative system in which the track rails and earth need not be employed as conductors. Our work in this direction is of an eminently practical character, not only retaining all of the good elements of the "track return" system but involving a new feature in the line of securing safety, viz., the reversal of direction of leakage currents from that taken by the motor current in passing through the negative switch, thus guaranteeing the "opening" of the switch and consequent discharge of the current from the street surface upon the passing of the car.

To fully understand the method of accomplishing the above features, reference is made to diagram D, where R R^1 represent the tram rails; SC^1, SC^3, SC^5, etc., one line of sectional rails; SC^2, SC^4, and SC^6 another line of sectional rails, and B^1, B^2, B^3, etc., contact points for delivering the positive current, the arrangement of conductors being clearly shown in Fig. 2, which represents a cross section of the roadbed.

It will be noticed upon examination of the diagram that when the switch M^1, for instance, is open, as shown, the positive main conductor and the negative main conductor are connected only to carbon contacts in the switch itself, there being no permanent connection between the sectional conductors or the tram rails and the negative main.

It will also be noticed that the current for energizing the electro-magnetic switches (see magnet M^2) flows from the track rails through the switch coils to one of the sectional conductors belonging to the row SC^1, SC^3, SC^5, etc.

Any leakage from the contact point B^3 would have a tendency to flow from said point to sectional conductor SC^3, then through the switch coil in the opposite direction, demagnetizing the same, to the track rail and to the positive sectional conductor SC^4, which is the negative service conductor; from which it will be fully understood that any leakage currents, after the car has passed, have a tendency to quickly open the electro-magnetic switch.

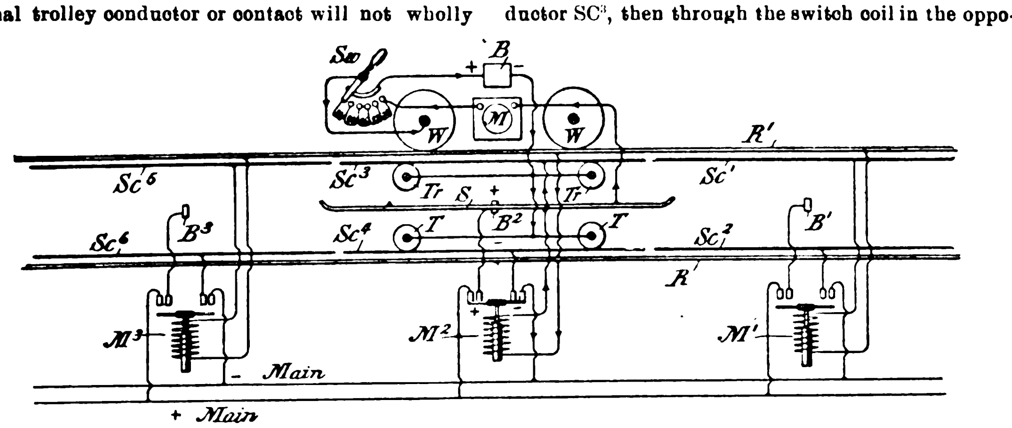

DIAGRAM D.

There has been a deal of superficial talk about the destruction of gas, water and other pipes by vagrant currents from the track rails when these are used as the return conductor. It is true that in the earlier equipments of the trolley roads too little attention was paid to securing a thoroughly good bonding of the rails and otherwise providing for giving them a sufficient conducting capacity, and that under such conditions the electric current seeking a pathway of lower resistance would traverse any contiguous conducting body, thereby causing more or less injury thereto through electrolytic action. When, however, this fact had once been made clearly manifest, additional attention was given to consolidating the rails by electric binding and otherwise, so as to give ample conducting capacity, with the natural result of so minimizing the vagrant currents as to well nigh eliminate their destructive effect; in fact, notwithstanding much that has been said of late upon this subject, it is an open question whether the evil actually exists where intelligent work has been done in laying the track rails. If, however, it is held to be desirable to have an absolute guarantee against such action it is not at all necessary to abandon the simpler system of a single wire conductor and track return and go to the complex two conductor system. It is quite within the electrical engineer's ability to completely eradicate the defect by the simple means of employing asphaltum about the base and sides of the rails when they are laid; the insulation thus afforded, though not of high quality, would yet be ample to care for the comparatively slight tendency of the current to leave the track rails and seek other conductive bodies.

The importance of preserving a smooth and unobstructed street surface is far greater than that of safeguarding a wholly problematical injury to gas or water mains, but there is, I repeat, absolutely no necessity of incurring either objectionable condition. Moreover, the cost of so insulating the rails as to eliminate all leakage would be trifling in comparison with the laying of a system of double conductors.

CONCLUSION.

Having thus encountered and overcome every possible obstacle, whether raised by virtue of our own foresight, the criticism of others or the operation of the system upon experimental trial, we determined to put it in practical operation upon a prominent New York street and prove the complete efficacy of all its factors "in the eye and under the nose" of railway managers, municipal authority and the public at large. This was done, and the demonstration, continuing over a period of eight months, proved conclusively that the system was reliable, economical and safe in all weathers and under all conditions of street surface. The sole criticism—one evolved, by the way, more from a predetermined intent to condemn than upon an honest judgment—was as to the physical obstructions of the streets by the two rows of buttons then employed in the system as the contact points. This criticism had a colorable ground under the conditions with which the work was environed, which were:

1st. The work was done in the winter season with frost in the ground.

2d. The buttons were founded upon the same unyielding base as the track rails in order to keep their top surface in the same plane as the track rails. The pavement in turn was founded upon sand. The inevitable consequence was a settling of the pavement on the disappearance of frost and a consequent considerable protruding of the buttons above the street surface, thus creating an objectionable obstruction to horse and wagon traffic.

The simple remedy for this fault was, of course, to give to the street pavement as complete and satisfactory foundation as was had by the buttons themselves and as is done in cable and open conduit work; but the critics of the system were not seeking light, they were after damnatory points, and though compelled to admit the satisfactory operation of the system, its safety, etc., and even that the buttons would not be objectionable upon the street of a European city where pavements were better laid, they adhered to the conclusion that upon our streets the buttons would be condemned by municipal authority.

While still combating this view and insisting upon the entire feasibility of so consolidating the buttons and the pavement as to maintain their surfaces always in the same plane, we have, neverthe-

less, in pursuance of our policy of confronting every hostile and prejudiced criticism with a complete antidote, sought and found a way and means of dispensing with buttons altogether, substituting therefor simply a single third rail, sectionally divided and so laid as to ensure its perpetual identity with the track rails themselves.

In accomplishing this without abandonment of any of the valuable factors incidental to the button system, Mr. Lundell has evolved an invention which may yet prove to be the "key" to the whole problem, particularly in view of the fact that it not only simplifies the system but materially reduces its cost. A description of this invention unfortunately cannot now be given, as the patents are still pending.

An important quality of the surface contact system is its extreme flexibility. Unlike the open conduit system all its operative parts are on the surface; it is, therefore, entirely feasible to pass at full speed from the surface contacts to an overhead trolley and vice versa. There is no "plow" or other incumbrance to remove.

A storage battery may be likewise combined with the system to operate the cars over unequipped portions of a line. The battery need not be removed from the car for charging as it is being constantly charged while passing over the equipped sections.

The opinions of Lord Kelvin and the late Dr. John Hopkinson, the one the greatest theoretical authority in the world and the other undoubtedly the best authority on practical application of electricity, attest and support the verbal expressions in support of the system made by such authorities as Thomas A. Edison, Frank J. Sprague and others. Dr. Hopkinson, in his advisory capacity as consulting engineer for English and Continental railways, strongly recommended the system to at least one of his clients, who now only awaits Parliamentary action to give it a practical trial.

The railway manager who first applies this system will achieve more in the way of ridding our streets of the objectionable overhead wires than have all the laws that have been enacted for this purpose.

THE ELECTRIC MOTO-VEHICLE.*

BY C. E. WOODS.

It gives me great pleasure to be honored with an invitation to express my observations and experiences in the development of the moto-vehicle before a body of men who have a professional interest in the question involved almost if not quite as keen as my own; for the development of the moto-vehicle—and I would like here to call attention to the fact that the many other names applied to self-propelled vehicles seem to me to be misnomers. Automobile is all right in France. Autocar is probably correct in England, neither one of which, it seems to me, is wide enough in its application for America. Motocycle is misleading, as it throws the mind away from a carriage production, and horseless carriage is brutal to say the least. It retains the memory of the very thing we wish to eliminate and reminds me of a little incident that occurred to a gentleman not long since while running a moto-vehicle on the street. One of our little street Arabs stood on the curb stone and as the carriage rolled by he looked up at the driver and said: "You needn't think you're so much, Mister, for you ain't the only one who ain't got no horse." I think it is desirable in a proposition of this kind to cast out all memory of a condition of affairs which in no wise applies to a new means of propulsion—as well say "horseless" when speaking of the trolley car. Moto-vehicle, a term which I have used almost exclusively in my business, seems to be a name that covers the whole field in this work as it implies any form of motor power or any class of vehicle construction to which such power may be applied, and I sincerely trust to see its general adoption in the near future.

But to resume: The development of the moto-vehicle has been an engineering proposition pure and simple both in its electrical and mechanical phases, points in which have required the same careful consideration for operation, cost of production, adaptability and utility as all other engineering propositions of the day have required; and it is not, as many suppose, confined to the narrow realms of mere invention. The prime principles employed in the construction and operation of a moto-vehicle are units well known in all other classes of engineering work, and it has been an adaptation of already existing elements to a new purpose rather than the creation of anything new in its entirety for some specific purpose; in addition to which, the carriage-maker's art has had to be investigated and the various styles, finish and contour used by it harmonized with a new condition of affairs in carriage building and designing. In this particular, I wish to express very briefly my experience, which has covered some three years and which has been gathered from all classes in my efforts to locate and predicate a market for moto-vehicles.

The development of this is not confined, as many suppose, to the creation of one or two types of vehicles to which power may be applied with the idea that, a la bicycle fashion, they would fill the requirements of the market. The cost of these vehicles necessarily demands solicitation for business from a class of people who have been users of fine carriages to a greater or less extent, and unless they can have the same diversity of design, the same luxury of appointment and finish, and the same easy riding carriage that they have always been habituated to, the proposition does not meet their wants and the market becomes limited. My work, and I notice that of others, is now towards the development and perfection of a general line of vehicles rather than toward some one or two specific forms of so-called machines. As a general thing, the less the word "machine" is used in the market the more satisfactory it is to the prospective purchaser, for he buys his carriage not because it goes without a horse, not because he wants conspicuousness or novel advertising on the street, but because he wants a carriage for himself and family to ride in in exactly the same sense that he has always purchased a carriage; and his first attraction to and admiration for a moto-vehicle is its independence of manipulation, its more rapid transit, and the refinement attaching to the use of such a vehicle by the absence of anything in the animal kingdom as a propelling power.

In the commercial world its economy and utility are the prime factors for consideration, though at the present moment some considerable importance is attached to its value as an advertising medium; but this valuation is a very unstable affair and will have a very short life, and the real question with the merchant is the economy of using these vehicles as compared with already existing conditions. Unfortunately, experience of any magnitude in this direction has not, as yet, been acquired, although from present results some few figures can be fairly well estimated which will be given further on.

As one looks over the colossal achievements of engineers in the last fifty years and the industrial revolution which they have brought about, and then in connection with this thinks of the still undeveloped possibilities in all directions, it is very hard to think of the moto-vehicle and its future without at times indulging in a little speculation as to its ultimate issue and the bearing it will have on both domestic and commercial life; and if its development, adaptation and application are to be in anything like the ratio that applied electrics have shown in the last ten years, speculation almost unconsciously becomes to us a reality when we consider the conditions as they now exist and compare them with the conditions which may be made to exist by its general introduction and adaptation.

To illustrate: Twenty thousand carriage-makers are required to-day to fill the market demands for vehicles in this country as required for road and street transportation. A little over 30 per cent. of the total animal power used in this transportation is required in the cultivation of the soil to obtain fuel for this power and to transport such means of maintenance and stable refuse from point to point. This means, broadly speaking, that animal power has in itself but about 70 per cent. efficiency in its application. Further, horse power cannot be worked at a greater average than about five hours or twenty miles per day, which as compared with mechanical applications of any form puts such power into a very low figure of utility. Under such conditions of operation, this power unit has a depreciation of not less than 20 per cent. per annum, and from large users of horses in express companies, large liveries, etc., the depreciation has been given me as about 33 per cent.—either of which figures is far in excess of any of our good mechanical or electrical propositions of the day.

These startling facts and figures bring us very close to an understanding of the possibilities for the moto-vehicle as an industrial feature, and we cannot under such circumstances deny the brilliant outlook it has for the future. The sanitary conditions attendant on its use, its lesser cost of maintenance, its greater mileage capacity, its more rapid transit, its lesser space occupied in the stable and on the street, its freedom from expense when not in use, all put together retires entirely the objections which at first appear as to its greater initial cost. The possibilities this vehicle opens up for road and street improvement and the low cost of maintenance of same should be items of great interest to municipalities, counties and States. Streets will have a capacity for double the amount of vehicles without any increased congestion, will be freed from the continual pecking of iron feet which are the main causes of their rapid deterioration, and sewers will perform their functions without being continually clogged up with refuse matter. With iron feet removed and rubber tires introduced exclusively, road and street construction should be reduced to one-half and maintenance to one quarter of its present cost. By this, the possibility of building and maintaining a roadway across country from city to city on which only such vehicles in connection with bicycles will be allowed to run becomes patent to our understanding, and the day will come when States and counties will be called upon to consider such roads. But to come back from speculation to reality. The greater first cost of these vehicles is a necessity which is very readily understood, as the vehicle part itself, for a first item, is necessarily more expensive for the reason that when it comes to carrying twice or three times the vehicle ordinarily carried, to running it twice or three times as fast as the horse drawn vehicle under exactly the same conditions of road and street, it means quite a different proposition in vehicle construction without reference to its electrical and mechanical features.

The necessity and durability of rubber tires for traction, noiselessness and protection to motors and batteries goes unchallenged, as does the absolute necessity of reducing all friction losses by the introduction of either ball or roller bearings in all of the moving parts; all of which are much more costly than ordinary carriage construction, but by virtue of which depreciation is very much reduced over the ordinary vehicle and an interchangeability made practicable in all of the wearing parts. These conditions, coupled with the first cost of motors, batteries and et ceteras, will never put the selling price of the moto-vehicle on a par with the hundred dollar buggy, as some people seem to imagine the dim future holds a possibility of, but will put its durability far in excess of such vehicle.

In reviewing conditions in other directions that

* Read before the Chicago Electrical Association, Nov. 18, 1898.

have led up to a possible perfection of the moto-vehicle, we can almost trace a sort of evolutionary wheel within a wheel progress that has all the time been tending toward its development. Other means of conveyance than by animal power, as by railroad, street car and bicycle, have given birth to a desire on the part of the public for any and all kinds of mechanical conveyance. With this came the perfection of rubber tire application on vehicles, which were first used for their noiselessness and which made possible the introduction of ball bearing axles, into carriage construction—two features without which the application of motor power would be almost prohibitive.

With the perfection of this came a gradual development of the moto-vehicle in its many phases, until to day we have what can be pronounced a successful issue in its practicability with an ever-increasing inquiry and demand from all over the world concerning its use and adaptability to personal and commercial wants.

This development, like all other propositions of kindred nature, was necessarily experimental in its initial steps and unfortunately led to many premature and erroneous conclusions regarding possibilities in its use and for a long time was not considered susceptible to any general application, and while with some people this first false impression has been retained, as a general thing its wide range of possible usefulness is well conceded, especially by the engineering fraternities of the country.

(To be continued.)

Carbon Arc Vapors.

Messrs. E. Merritt and Oscar M. Stewart give in the current number of the *Physical Review* some most interesting experiments on the conducting properties of the vapors arising from the electric arc between two carbon points. In the series of experiments carried out by the authors, the known properties of gases ionized by the action of X rays were kept in view in order that the resemblances and differences between the two classes of phenomena might be brought out. The various experiments in discharging electrodes by means of the arc vapors, and as to the length of time which their properties required, are too long to refer to in detail. The results of the experiments, which the authors consider as preliminary only, says the *Electrical Engineer*, London, may be briefly summarized as follows:

(1) The vapors from the carbon arc possess the power of discharging electrified bodies with which they are brought in contact. In general, the electrical properties of these vapors are similar to those of gases that have been acted on by X-rays, or to the gases from a flame. Except at low potentials the rate of discharge is not proportional to the potential, but approaches a limiting value as the potential is raised. (2) This discharging power is retained even after the vapors have been passed through long tubes of glass or metal, and lasts for at least 10 seconds. (3) When caused to pass between a charged conductor and one that is grounded, the vapors in large part lose their conducting power. A similar result is obtained by passing the vapors through loosely packed asbestos wool. (4) After passing between two grounded conductors, these being only a short distance apart, the vapors are found to discharge a negatively electrified body more rapidly than one charged positively. In this respect their behavior is similar to that of gases that have been ionized by the action of X-rays.

The explanation of the phenomenon is probably that suggested by Zeleny—namely, that the negative ions diffuse more rapidly than the positive ones. (5) Positive and negative charges are in general dissipated by the vapors with equal rapidity. But experiments made with a vertical enclosed arc show that gases taken from near the lower carbon have unequal discharging powers for the two electricities; in this case that charge which is of the same sign as the lower carbon is dissipated less rapidly. This is true whether the lower carbon is positive or negative; and the effect is not altered by connecting either carbon with the earth. (6) If air or oxygen that has been saturated with water vapor is introduced into the enclosure containing the arc, the conducting power of the arc vapors is greatly increased. But this effect can no longer be observed when the body to be discharged is at a considerable distance from the arc.

LONG DISTANCE TRANSMISSION OF POWER.*

BY C. RICE DOOLEY.

So rapid has been the growth of manufacturing industry in the United States that the subject of power has become one of vital importance. For years the direct utilization of the power of waterfalls and steam plants has been almost the exclusive practice in operating factory tools. To these animal power has given way. Are we finally to see the electric current supersede steam?

Since the advent of greatly improved machinery for developing electricity, engineers have given more attention to this force. Until within the last decade the transmission of electric energy over long distances was not practicable, therefore prior to this time the electric generator with its source of power had to be located near the place of power consumption. This, of course, necessitated the use of an engine, excepting in a few cases, where water power could be obtained, and as available water powers are comparatively scarce, the demand for steam engines was materially affected. For this reason every small lighting plant and every electrically operated factory had to be fully equipped with its own source of power. The advantages of such an arrangement are not great, for the engine that drives the dynamo must be of sufficient power to do the work which the electric current performs; therefore it is more economical for the small factory to apply the power of the engine directly to the machine tools. However, in large installations, the convenience of distributing power through wires over that of mechanical appliances often warrants the use of electric power, even where an engine has to be maintained to supply the mechanical power for generating it. It is evident, therefore, that for small shops and factories electricity could, in the past, have been of no benefit unless these establishments were fortunately situated near water powers.

With the development of larger and more efficient dynamos the effort has been to establish central power stations for transmitting energy electrically over large territories. This system has attained its highest development in the harnessing of natural cataracts.

In speaking of electric energy the engineer thinks of two things: First, the amount of electricity flowing through the wire; second, the force with which it is being driven along. This force is commonly known as voltage, while we will refer to the electricity flowing as the current; thus we speak of a certain current transmitted at so many volts. By experiment we know that the main loss of energy is due to heat radiation from the transmission lines. Also, it has been demonstrated that this heat varies directly as the resistance offered to the current and as the square of the value of the current. From this we see that if only a small amount of current is conducted the per cent. of loss is very much reduced; the problem is, then, to transmit the electric energy in the form of a small current and at the same time provide for the development of a large amount of power where it is to be utilized. To do this the practice is to generate an electric current at a moderate voltage and, by means of suitable apparatus, convert it into a small current at high voltage. This high voltage current is transmitted to the point of utilization where the electric energy undergoes a reverse transformation which brings it to its original condition and to one much better adapted to the propelling of machinery.

The use of a small current at high voltage is analogous to that of a small water pipe conveying water under high pressure. Suppose two pipes varying widely in diameter to conduct water from "a" to "b." Now, in order to transmit the same volume of water by each in the same time the water in the small pipe must evidently have a much greater pressure, or rather velocity. These two pipes may be made to fill two equal reservoirs in the same time and thus each made to do the same work. Just so in the case of electric transmission; the same power can be conveyed either by a large current at low voltage or by a low current at high voltage, but as the heating is much less in the latter case it is the method that is commonly used—in fact it has rendered the long distance transmission of electric energy possible.

Upon this principle the great long distance power transmission plant was constructed at Niagara Falls. Nature has concentrated a vast amount of energy at this one point, and at last man has succeeded in developing a practical method for its distribution, in part at least. In the year 1894 the Niagara Falls Power Company saw the completion of its great project, and now this plant furnishes almost the entire city of Buffalo, over twenty miles distant, with electric power. The generators produce a current at 2,200 volts which is transformed to 11,000 before leaving the plant. Then at Buffalo the voltage is reduced to 500, at which pressure the electric energy is used to drive the street cars of the city, for lighting purposes and for local distribution. Although the Niagara plant was by no means the first of its kind, or even the first for the purpose of long distance transmission, yet at one time it was by far the largest one and operated on such a large scale that the era of long distance transmission lines will doubtless be properly dated from the time of its completion. Since the completion of the plant many factories have located near Niagara, and among these we find "The Niagara Electro-Chemical Works" and the aluminum factories which use the current directly in obtaining this product; also "The Buffalo Railway Co." employs the Niagara power to drive its street cars.

The success of this great power plant seems to have decided the question of central stations driven by water power, for scarcely a season passes without the periodicals containing detailed accounts of late water power generating plants furnishing electric current at high voltages within a radius of several miles. We find them all over the United States; for instance, at Lewiston, Idaho, a town situated on the Asotin river, is quite a large station. The stream has a fall of sixty-five feet to the mile and by means of conducting channels the water is made to descend perpendicularly one hundred feet on the turbines. The current generated is transmitted at ten thousand volts and at the terminals of the line is used at five hundred volts to drive machinery and for lighting purposes. Again we find another on Apple river in Wisconsin. There the current is generated at six thousand volts and transmitted directly from the machine for a distance of seven miles where the voltage is reduced to two hundred. This power is largely used to operate grain elevators as well as for lighting purposes. We also find many such plants in the Eastern States, and one I would especially mention is located on the Hudson river about seventeen miles from Schenectady, N. Y. Schenectady is the location of the largest electrical manufactory in the United States, and the entire institution was until recently entirely operated by steam. The electrical energy is transmitted from the Hudson to Schenectady at a voltage of ten thousand.

But the United States is not alone in this advance-

*From *The Purdue Exponent.*

ment, for we find extensive generating plants in other countries; for instance, at Kootenay, B. C., twenty-five thousand horse power is generated by turbine wheels. The energy is conducted thirty-one miles at twenty thousand volts pressure and then reduced to twenty hundred for commercial purposes. Even in Brazil, S. A., we find a few central power stations. One is operated by a one hundred and fifty foot water head which transmits the current at four thousand volts for several miles where it is used to propel a street car system.

Many other interesting plants might be cited, but these few will show the favor with which this scheme of power transmission is meeting. Centralized power is undoubtedly the best method of making electricity the servant of all institutions both great and small.

Electrical Haulage on English Canals.

The system of electrical canal haulage which is about to be tested on one of the Northern canals by a Westminster firm, says *Industries and Iron*, is of some interest. In it the motors are independent of the barges, for they haul them by means of ropes. An aerial railway consisting of two steel rails braced together and supported at a height of 9 ft. or 10 ft. above the towing path by means of cast iron brackets, at intervals of about 30 ft., is laid along the canal banks. This is the running track for the electric hauler, which consists of a motor mounted on a four-wheel carriage. Two of the wheels run on the upper surface of the rail and two beneath. All the wheels are drivers. The motor is of the ordinary direct-current series-wound type. The tractive force required to tow a barge carrying 100 tons on a canal of ordinary cross-section at the rate of $2\frac{1}{2}$ miles per hour is from 250 to 300 lbs. The brake horse-power is thus—

$$\text{B. H. P.} = \frac{2.5 \times 5{,}280 \times 300}{60 \times 33{,}000} = 2.$$

But the hauling apparatus must be able to extort 600 lbs. and would weigh 300 lbs., and the weight of the motor or carriage would not exceed 900 lbs. The estimated cost by horse haulage at $2\frac{1}{2}$ miles per hour is .077 penny per ton per mile, and the cost of electrical haulage .032 penny per ton per mile.

A Trolley System for Paris.

The municipal authorities of Paris have up to the present set their face against the introduction of the trolley, so the *Electrician* of London informs us. The line from Aubervilliers to the Place de la République runs only as far as the fortifications on the trolley system, but a new line from Charenton to the Bastile has now actually brought the trolley wires within the gates of the city.

The length of the line is 3.8 miles, and it is all on the overhead trolley system, with the exception of two sections, aggregating half a mile, on which the underground conduit is employed. Three Thomson-Houston compound-wound generators (one serving as reserve), each of 150 kilowatts capacity, furnish the power. These are driven through belting by single Farcot non-condensing engines. The station pressure is 550 volts. Three semi-tubular Meunier boilers, with a heating surface of 6,500 sq. ft., furnish steam at 100 lb. per square inch pressure. These boilers work under forced draught on M. Prat's system, and a chimney 56 ft. high is found amply sufficient. There is a battery of 250 cells, with a capacity of 350 ampere hours, used for supplying the conduit sections of the line which are electrically isolated from the remainder. The battery is charged by one of the generators, a special switch being provided to short-circuit the series windings.

The track is double throughout, made up of 90 lb. rails with Falk cast-welded joints. In nearly all cases the posts supporting the trolley wire are in the center of the street and span wires are not used. The posts each carry two 5 ampere arcs on brackets, the lamps being connected five in series across the terminals of the battery. The conduit part of the lines is similar to that in use in Ninth street, Washington, with a slot 1 inch wide. There are in all 18 cars, with single-reduction motors, and differing but little from the usual Thomson-Houston construction.

THE WARREN ELECTRIC & SPECIALTY COMPANY'S PLEASANT OPENING OF A NEW FACTORY.

The *Daily Chronicle* of Warren, O., gives the following account of the pleasant entertainment furnished by the Warren Electric & Specialty Company to their employes to celebrate the opening of an important annex to their works:

"Ever since the formation of the Warren Electric & Specialty Company the good feeling between employer and employe has been a matter of note. Each year the company in some way manifests to its employes the existence of a special interest. The management recently saw a chance to give every employe a pleasant evening of enjoyment, and accordingly the plan was carried out. The company have just erected a large two-story building to be used for a machine shop and the manufacture of electrical apparatus. The programme was to dedicate this building by giving a supper to the entire force, to be followed by a dance, and it was carried out to the dot. At 5:30 on the night of the 22d inst. the 128 employes filed into the impromptu banquet room and took seats at the tables. Officials of the company and several other stockholders, accompanied by their wives and children and a few friends, were seated at the center table. The Anti-Trust football team filed in and took their places at a specially arranged table. Previous to sitting down they yelled their football slogan which is:

> "Win we will, win we must
> For we belong to the Anti-Trust.
> Rah! Rah! Tiger, Sis. boom ah!
> W. E. S. Company—Rah! Rah! Rah!

"The ladies of the Friendly Union served an excellent repast, and all did justice to the tempting viands.

"Pres. T. H. Gillmer was called upon for a speech and responded in part as follows: 'Six years ago, or on November 19, 1892, the Warren Electric & Specialty Company was organized; there were not many present at the christening, only six. Soon we began business, and at first we had but few employes on the pay roll—which was lucky for us; but during the years we have steadily increased our business and now have 128 persons on the roll—and I am informed that I am not included in the number. For 300 days in the year you work hard; you do the duty assigned, and so far you have been satisfied to do the work given. I think a company that appreciates the work of its laborers will lose nothing by giving them an entertainment of some kind, as we have done to-night. Such firms succeed. I am not egotistical when I say this firm has succeeded, that our business has increased; and this is due greatly to the aid and co-operation you have given us. We have had no labor trouble and we hope it will continue thus. We have planned further amusement for you upstairs and hope you will enjoy yourselves, for by so doing you will please us. I thank you.'

"Three rousing cheers were then given for the Warren Electric & Specialty Company and its officers."

Dancing followed, and a cake walk, recitations, etc., added to the enjoyment of the merry gathering.

Proposals Invited.

The U. S. Navy Department, through the Bureau of Yards and Docks, is inviting sealed proposals until December 17 for extending the electric light system at the New York Navy Yard. At the same time and place proposals will also be received for enlarging the wiring system at the same Navy Yard. Specifications, blank forms of proposal, a wiring plan and a general plan will be forwarded to prospective bidders upon application to the Bureau of Yards and Docks, Washington, D. C., or to the Commandant of the U. S. Navy Yard, Brooklyn, N. Y.

The Interior Department, through the office of Indian Affairs, is inviting sealed proposals until December 20, for furnishing and delivering the necessary materials and labor required in the construction and completion of an electric light plant at the Indian Industrial School at Mt. Pleasant, Mich. Plans, specifications and instructions to bidders may be examined at the Indian Warehouse, 1,602 State street, Chicago; the Builders & Traders' Exchange, Omaha, Neb., and at the school. Any additional information may be obtained upon application to W. A. Jones, Commissioner of Indian Affairs, Washington, D. C.

American Institute of Electrical Engineers.

The 129th meeting of the Institute was held at 12 West 31st street, New York, on Wednesday evening, November 23, President Kennelly in the chair. The paper of the evening, on "The Design of Transformers," by F. W. Carter of London, England, was read by Prof. W. S. Franklin of Lehigh University in the absence of the author. It was discussed by Messrs. Franklin, W. B. Jackson, Wolcott, Henshaw, Torchio and others.

At the meeting of the Executive Committee in the afternoon the following associate members were elected:

Cleveland Abbe, Professor of Meteorolgy, Weather Bureau, Washington, D. C.

John Cassidy, Superintendent Mutual Telephone Co., Honolulu.

James Francis Cosgrove, Head of Locomotive Engineering Department International Correspondence School, Scranton, Pa.

Donald Hume Fry, Assistant to Robt. McF. Doble, San Francisco.

James Hamilton, Patent Attorney and Expert in Patent Causes, Boston, Mass.

Bernard Hoffman, New York Telephone Co., New York City.

Harry D. James, Expert Draughtsman, Otis Bros. & Co., Yonkers, N. Y.

S. L. G. Knox, First Asst. Engineer, Crocker-Wheeler Electric Co., Montclair, N. J.

Howard Wallace Leitch, Switchboard Regulator, Edison Elect. Illuminating Co., Brooklyn, N. Y.

R. W. Lohmann, Electrical Engineer, Oakland, Cal.

C. Stowe Reno, Electrical Engineer, Triumph Electric Co., Cincinnati, Ohio.

R. H. Sperling, Assistant Engineer, British Columbia Electric Railway Co., Victoria, B. C.

James Wilkinson, Station Manager and Chief Engineer, Consolidated Electric Light Co., Birmingham, Ala.

A. Wilford Zahn, Electrical Engineer and Supt., Manhattan Light, Heat & Power Co., St. Paul, Minn.

The following associate members were transferred to full membership:

Franklin Robert Anson, Secretary and Manager, Salem Light & Traction Co., Salem, Oregon.

Sidney Hand Browne, Consulting Electrical Engineer, Baltimore, Md.

A. E. Brooke Ridley, Agent & Electrical Engineer, Siemens & Halske Electric Co., San Francisco.

The Committee on Co-operative Research having completed the first stage of its work, has sent various collegiate electrical engineering departments an explanatory circular submitting twenty-seven subjects for investigation.

An Electrical Exhibition in 1899.

We have received the following announcement for publication:

Editor ELECTRICITY.

DEAR SIR: At the annual meeting of stockholders of the Electrical Exhibition Company, held on the 21st inst., it was unanimously decided to hold another Electrical Exhibition in this city in 1899.

The following officers and directors were elected: C. O. Baker, Jr., president; F. W. Roebling, vice-president; Geo. F. Porter, secretary and treasurer; Marcus Nathan, general manager; H. H. Harrison, L. F. Requa, J. W. Godfrey, C. A. Lieb. Very truly yours,

ELECTRICAL EXHIBITION CO.

New York, Nov. 22, 1898.

LEGAL NOTES.

The Supreme Court at Jefferson City, Mo., has declared invalid and inoperative the Julian public franchise law (for the sale of franchises by the city). The decision was rendered in the quo warranto case against the West Side Electric Railway of Kansas City, wherein the Attorney General of the State brought mandamus proceedings against the street railroad company to compel it to show why its franchise had not been granted under the provisions of the Julian law. The opinion, which was written by Judge Williams, declares the law is inoperative because it is indefinite and vague in its provisions. The act of the court in knocking out this law precludes the sale of street railroad, telephone, telegraph, and in fact all public service franchises by the city.

The Supreme Court of Oregon held, in the case of Perham vs. Portland General Electric Company, that the doctrine that the placing of electric wires known to be dangerous at a place where others are lawfully entitled to be constitutes negligence was properly applied to wires strung over a bridge where workmen in repairing the bridge came in contact with them, and that the apparent perfect insulation of the wires amounted to an invitation to risk contact with them when the wires were placed where persons while performing their duties might come in contact with them.

The Court of Appeals at Frankfort, Ky., on the 23d inst., affirmed the judgment of the Franklin Fiscal Court in the corporation indictment cases. Indictments were filed in the lower court against 120 of the largest corporations in Kentucky, including express, telegraph, telephone, water, gas, street car, electric light, bridge and other corporations, for failing to file reports and schedules of property in that State and business done. The statute provides a penalty of $1,000, and $50 a day additional for each day of such delinquency. The lower court returned verdicts for the State and the Court of Appeals sustains the verdicts, holding that the statute is constitutional and that failure to report is a violation, and that the corporations cannot be excused on technical grounds. The decision will eventually amount to more than a half million dollars in fines to the State, and it is said by the management of some corporations will amount to confiscation of their property and force them out of business.

The Appellate Division of the New York Supreme Court for the Second Department held, in the case of O'Flaherty vs. Nassau Electric Railroad Company, reported in New York *Law Journal*, that the falling of a trolley wire into the street raises a presumption of negligence on the part of the company which maintains such wire that will create a liability for injuries sustained by a passer-by unless the conditions are satisfactorily explained so as to overcome such presumption of negligence, and that the testimony of the defendant's employees regarding a system of inspection of such wires will not relieve the defendant of this presumption of negligence as matter of law, but that the witnesses being interested persons who might have a motive of shielding themselves from blame their testimony presents a question for the jury. The court further held that where the testimony shows the use of an automatic device for cutting off the current when a wire falls to the ground the communication of a shock to a passer-by will authorize a finding that such appliances were not in working order at the time of the accident.

The Kings County Electric Light and Power Company.

The Brooklyn *Eagle* says: "The management of the Kings County Electric Light & Power Company has decided to retain General Superintendent F. S. Barstow of the Edison Electric Illuminating Company as general manager of the recently consolidated company. Mr. Barstow has been for many years connected with the Edison Company and has an enviable record for his thorough knowledge of the electrical business as well as for executive ability of a high order. E. F. Peck, who has been the secretary of the Kings County Company, has been appointed assistant general superintendent. Mr. Peck has been interested in electric matters in Brooklyn for years and has been connected with the Citizen, Edison and Kings County Companies. No other changes in the personnel of the management will be made for some weeks and not until the report now being prepared by A. M. Young has been presented and acted on by the Board of Directors. The changes contemplated, however, are said to be radical in character and will be in the line of greater economy in management."

CANADIAN NOTES.

Mr. C. J. Ballantyne of Honolulu, formerly a resident of Ottawa, is now in the latter city. He left Ottawa and went west in 1882, finally locating in Honolulu. Recently he organized a company and bought the franchise to operate an electric railway in Honolulu. He is now on a visit to the leading American and Canadian cities with the object of purchasing a plant and also studying the systems upon which electric roads are operated. Speaking of Hawaii, Mr. Ballantyne said that the people are well satisfied with their status under American protection, and he feels sure that the country will progress at a much greater rate than previously.

The Metropolitan Electric Company will be supplying electric light, power and heat to the city of Ottawa probably by the end of March next. The survey of the company's water power at the Britannia Rapids, about ten miles from Ottawa, has been completed, and everything is now ready for the work of constructing the power house and arranging for the transmission of electricity. Tenders have been called for and about the first of December operations will be started. The Metropolitan Company has two lines under construction for the transmission of the electricity. Only one of these, however, will be operated at present. Through a point of land on the Ontario shore of the Ottawa river which juts out into the Britannia Rapids a canal about 125 yards long and 20 feet wide will be made. At the foot of this canal will be built the power house, and the water from the rapids will be concentrated in the canal.

The Lunenburg Gas Company, of Lunenberg, Nova Scotia, is changing its electric plant from steam to water power. It has a 16 foot dam nearly completed on the Mush-Mush river at Mahone, eight miles from Lunenburg. The pole line is completed and is said to be the finest in that part of Nova Scotia. The water wheel is from the works of the S. Morgan Smith Company, York, Pa., and is one of their well-known "New Success" turbines. The company will light the town of Mahone in addition to supplying light and power to Lunenburg.

THE NEWS.

What is Going On in the Electrical World.

STREET RAILWAYS.

Akron, O.—Gen. Samuel Thomas, of New York, president of the Akron Street Railway & Illuminating Company, who was here a few days ago, stated that the property of the company would be sold next month and the receivership terminated.

Attalla, Ala.—It is stated that Capt. J. M. Elliott, Jr., the owner of the dummy line running between Attalla, Alabama City and Gadsden, has made arrangements to convert the line into a trolley road, the power for which will be furnished by the Alabama Electric Power & Light Company.

Belding, Mich.—The Grand Rapids & Belding Traction Company have filed with the city clerk their acceptance of the franchise granted them by the Belding city council recently, under the terms of which they must have the road in operation inside of a year. The next step is to get a franchise in the city of Grand Rapids, which may cause some trouble.

Camden, N. J.—The promoters of the new elevated electric railway between Camden and Atlantic City have withdrawn their application for a franchise, owing to the opposition developed in the city council.

Chattanooga, Tenn.—Bonds to the amount of $200,000 have been issued for the construction of an electric railway line from this city to Chickamauga Park.

Derry, N. H.—At the coming session of the Legislature an attempt will be made to get a charter for an electric railroad running from Nashua through Londonderry to Derry.

Denver, Col.—There is some talk of the revival of the Lookout Mountain railway scheme. The top of Lookout Mountain is a most attractive place for a suburban resort. So fine a site for summer cottages is not to be found anywhere else near Denver. It is up among the pines and an electric line reaching the summit would place residents of the city within forty minutes' ride of the mountain top.—United States Commissioner Hinsdale has set a date for the sale of the Denver City cable and West End electric lines, which is December 15.

Jackson, Miss.—Work on the electric street road, after many unavoidable delays, has at last begun and will be pushed to completion. The Tennessee capitalists who are behind the enterprise expect to spend more than $100,000 on the car line and lighting systems, for both of which they hold a franchise.

Lincoln, N. J.—Silas D. Drake is the projector of a trolley road from Lincoln to Mizzen Peak, for which he asserts that he has secured right of way and also that the necessary funds are ready. Mizzen Peak is a high point in the first ridge of the Watchung Mountains and lies right back of Bound Brook. It is a beautiful place with a magnificent view and cool mountain breezes in the summer time. Mr. Drake's plan is to run a trolley road up the side of the mountain and convert Mizzen Peak into a summer home for New York business men.

Marysville, O.—The company which proposes to build an electric road to connect Marysville, Pharisburg, Magnetic Springs, Richwood and Delaware and later to connect with Columbus, has completed its organization by electing the following officers: W. A. Wright, president; J. P. Eubanks, secretary, and R. C. Turney, treasurer. Stock subscriptions will be immediately raised and the work on the road will begin about the first of April.

Niles, Mich.—The city council has granted the Michigan-Indiana Street Railway Company a thirty-year franchise to operate and maintain a street car system. The line, as proposed, is to run from South Bend to Benton Harbor, through Niles and Berrien Springs. According to the terms of the franchise the system must be completed within two years.

Northport, L. I.—It is reported here that the Long Island Railroad Company is going to build a trolley line between this village and the depot. Three of the officials recently visited Northport and were driven over the proposed route.

Peoria, Ill.—The long controversy over the leasing of the lake front to the railroads was brought to a close a few nights ago, when the city council, by a vote of 10 to 4, leased that ground to the Peoria & Pekin Traction Company and the Rock Island road for a term of fifty years. The city receives $500 a year and $500 a year for each additional railroad which may use the terminals. It is expected that four or five roads will come in.

Tacoma, Wash.—New York parties have been corresponding with some of our enterprising citizens in regard to a fast electric railway line between this city and Seattle, and it is believed the project will be carried out.

Utica, N. Y.—The Utica & Suburban Railway Company, having obtained a franchise from the highway commissioners, has put gangs of men at work on the construction of the electric railway which is to connect Utica and Rome.

Waterville, Me.—An effort is being made at Oakland to interest capital in the construction of an electric road from that village to this city, and the scheme is finding favor among the people. The argument is that ample and safe water power can be secured at Oakland, that the road would be only a little over five miles in length and that it could be operated at no greater expense than the one from here to Fairfield.

Wheeling, W. Va.—Steps are being taken to secure right of way for an electric road from Steubenville to Martin's Ferry, connecting with the Wheeling Railway at the latter point. The line will run twenty miles in a district well inhabited, connecting Wheeling, Bellaire, Bridgeport, Martin's Ferry, Yorkville, Highland City, Tiltonsville, Warrenton, Rush Run, Brilliant, Mingo and Steubenville.

Wichita, Kan.—A few men and teams have been put at work on the electric street railroad for which H. B. Church was granted a franchise several weeks ago. The work is under the direct supervision of manager W. O. Church.

Zanesville, O.—Judge Taft of the United States Circuit Court at Columbus has ordered the sale of the Zanesville Electric Railroad on January 3 next. Will Christy was appointed special master to make the sale.

LIGHTING.

Bellefontaine, O.—The Big Four railroad company will put in and operate an electric light plant of its own at its shops in this city and will light the yards, crossings, depot, offices, etc.

Bradford, O.—The electric light plant, which has been shut down for some time, was purchased on the 19th inst. by L. A. Dye, who will commence running it as soon as repairs are made.

Cincinnati, O.—A resolution requiring the Edison Company to put recording voltmeters upon its various lighting circuits in this city was presented at a recent

meeting of the lighting board and was referred to the committee on law.

Flint, Mich.—The People's Electric Light Company of this city intends to increase the capacity of its plant from 3,000 to 8,000 lights. The improvements contemplated will cost about $25,000.

Gadsden, Ala.—The Alabama Light & Power Company has been granted permission to construct and operate a light and power plant in Gadsden. The power house will be equipped with the very latest machinery and will cost $25,000. W. S. McCabe is president of the company.

Gainesville, Ga.—James P. Edwards of Augusta is making investigations as to the advisability of putting in an electric lighting plant in Gainesville. If he is assured of sufficient patronage he will erect a plant.

Greenfield, Ind.—The city council has purchased the plant of the Greenfield Electric Light & Power Company, paying therefor $16,000.

Hackensack, N. J.—The Hackensack Gas & Electric Company has absorbed the Englewood Gas Light Company, paying at the rate of $250 a share for the stock. The business of the company will be extended and gas and electric light will be furnished to a number of villages in the neighborhood of Englewood.

Houston, Tex.—The application of Blake Dupree, receiver for the Citizens' Electric Light Company, to purchase a new site for the location of the proposed new Citizens' electric light plant, has been granted by Judge Bryant of the Federal Court and the property will be purchased at once when the work of constructing the $150,000 plant will be begun. This plant will be of a capacity to furnish the entire city with electric lights.

Indianapolis, Ind.—The Chenoweth Electric Light & Power Company has made application to the Board of Works for permission to erect poles and wires for electric lighting outside of the mile square. D. A. Chenoweth, a member of the company, informed the board that the company intends to do commercial and domestic lighting.

Lawton, Mich.—A short time ago Lawton voted to bond the town for $5,000 for electric lights. It was carried by a large majority and the bonds were sold to the First National Bank of Paw Paw. Upon further examination the buyers of the bonds refused to take them because the election was held less than fourteen days after notice as is required in such cases by law. Another election is called for November 30.

Milwaukee, Wis.—C. E. Estabrook has sold the South Milwaukee electric light and power plant to a company known as the South Milwaukee Electric Light & Power Company. The sale includes all the machinery, franchise, etc. The price paid by the new company is said to have been in the neighborhood of $20,000, which was about the figure the entire plant was offered to the city for, in yearly payments, recently, the sale for which was knocked out by the mayor's veto. The new owners will operate the plant.

New Holland, Pa.—Eli Martin, a resident of this borough, has made a proposition to the borough council for erecting an electric plant and lighting the streets, and the indications are that it will be accepted. An electric power plant has been installed in the New Holland Silk Mill.

Northport, Ore.—W. R Lee and some Montana capitalists have been granted a franchise to build and operate in Northport an electric light system. Work must be commenced before December 1.

Oconto, Wis.—By the burning of the planing mills of the Citizens' Electric Light & Fuel Company, the city is left in darkness as the electric lighting plant was located in the mills. The insurance was only $18,000 while the loss was $60,000.

Owenton, Ky.—J. M. Riley, of Bracken county, Ky., and W. E Arnold, of Dayton, O, have made arrangements to start a large flour mill, and probably an electric light plant, at this place. The business men of the town have donated a site.

Pasadena, Cal.—The city trustees of Pasadena are figuring on owning their own electric light plant, and for that purpose have called for bids on six different sets of specifications. All bids are to be in by January 1.

Pierre, S D.—The council has decided to put in an electric light plant for city service. Power for the operation of the plant will be supplied from the gas well.

Provo, Utah.—A committee of council reported in favor of the city erecting an electric light plant and also recommended the purchase of the electric plant of Reed Smoot, not including his dynamo. The report was accepted by the council and a power site on the Timpanogas canal will be purchased.

Royal Oak, Mich.—William Helzinger of this place made a proposition to furnish the village with a number of 1,500 candle power electric lights at 20 cents per night, and the council has accepted it and granted him a five years franchise.

Savannah, Ga.—The council has passed ordinances granting equal rights to construct overhead and underground lighting systems to the Brush and the Edison Electric Illuminating companies. The latter is a new company in Savannah while the Brush Company has had a monopoly of the lighting business here for some years. The officers of the Edison Company are: Geo. J. Baldwin of Savannah, president; M. P. Clough of Boston, vice-president; W. Cameron Forbes, of Boston, treasurer, and W. W. Mackall of Savannah, treasurer.

San Francisco, Cal.—Judge Seawell rendered a decision here on the 16th inst. which promises to make future contracts for the lighting of streets and buildings in this city a subject of public competition. The decision was in a suit brought by the Mutual Electric Company against Mayor Phelan and the Board of Supervisors. It holds in effect that as long as the San Francisco Gas & Electric Company is permitted to maintain posts and poles for the stringing of overhead wires it is the legal duty of the Supervisors to grant the plaintiff corporation a similar privilege.

MANUFACTURING, ETC.

Ft. Wayne, Ind.—The Fort Wayne Electric Corporation has just shipped a 1,000 light dynamo and equipment to Chelsea, Mich., and a 125 arc light machine to Lowell, Mass. It also dispatched a car loaded with dynamos and station material, lamps, etc., for a large plant it is installing at Natchez, Miss., and shipped a 2,000-light dynamo to Dublin, Ga.

Pittsburg, Pa.—The Westinghouse Company it is said has contracts on hand for 262 electric railway motors and 8 generators for English railways.

Sharon, Pa.—The Aschman Steel Casting Company has decided to expend $20,000 on improvements in its plant. Two new electric cranes are to be placed in the works.

Shanghai, China.—The municipal council, by resolution passed recently, invites tenders for a concession for constructing and working about 23 miles of electric tramways (trolley system) in the streets of Shanghai. Plans may be seen and particulars obtained upon application to Blackall & Baldwin, 39 Cortlandt street, New York, or to Charles Mayne, municipal engineer, Shanghai. Tenders for the concession must be sent not later than the 15th of March, 1899, to J. O. P. Bland, secretary to the municipal council, Shanghai.

Warren, O.—The Warren Electric & Specialty Company has arranged for a large addition to its plant which will necessitate the employment of 50 more people.

POWER AND TRANSMISSION PLANTS.

Chicago.—Armour & Co. will change the motive power at their packing houses from steam to electricity believing the latter will prove much more convenient and economical. Work will soon begin on the power-house, and already some of the engines and dynamos have been purchased. The lighting system is also to be changed and simplified for the sake of economy and better illumination. The works have already been wired for 5,000 lights. There will be one 5,000 and two 3,000 light alternators installed as soon as possible, and more may be purchased. A cross-compound Corliss engine of 1,700 horse power is ready for the completion of the power house, and two generators of 2,400 electrical horse power are also about ready. The "Inter-Ocean" states that men well posted in the affairs of the packing houses at the yards are of the opinion that the departure of this firm means a like move on the part of the other large concerns.

COMPANY MATTERS.

Boston, Mass.—The Plymouth & Sandwich Street Railway Company has filed a certificate that 50 per cent. of its capital stock has been paid in, the whole having been subscribed. H. B. Taylor is president; W. H. Brine, treasurer; W. H. Hawley, clerk.—The Webster & Dudley Street Railway Company has filed its certificate that its entire capital has been paid in. E. S. Hill is president; John Flint, treasurer; Charles Haggerty, clerk.

Norwalk, O.—The Citizens' Electric Light & Power Company of this city has increased its capital stock from $30,000 to $70,000.

PERSONAL AND MISCELLANEA.

William E. Hale, treasurer and one of the largest stockholders of the Toledo Traction Company, died at his home in Chicago on the 16th inst. He was 65 years old. Mr. Hale was elected treasurer of the Toledo Traction Company when that corporation, having absorbed the Robison interests, was reorganized.

Alexander McAdie, forecast officer in the Weather Signal Office in New Orleans, has received notice of his selection as one of the editors of "Terrestrial Magnetism and Atmospheric Electricity," an international quarterly journal published in Cincinnati, London and Berlin.

The First Regiment Volunteer Engineers, Colonel Eugene Griffin, arrived at New York from Porto Rico on Thursday last in better condition than any other regiment that has returned from the seat of war. The regiment has received a sixty days' furlough, at the termination of which they will be mustered out, having made a record that will long be remembered to their credit.

The Street Railway Employes' Association of New Orleans, as we learn from the "Picayune," is planning for an innovation in connection with the Carnival that promises to add a very interesting feature. It is intended to give a carnival parade of street cars. The various car barns are taking up the matter and a committee has been appointed from each of the seven stations. There will probably be two cars from each station and one gotten up by the traction management. These cars will each be lighted with about 1,000 lights, which will make a magnificent display, as the largest number ever put on a car in New Orleans is 350. The seats will be taken out of summer cars and they will be made into floats and masked men will be placed on them. The affair will take place on the Saturday before Mardi Gras.

The Philadelphia "Inquirer" states that James F. McLaughlin, an electrical and mechanical engineer of Philadelphia, is preparing for a trip to Cuba and Porto Rico in the interest of some Philadelphia and New York capitalists who are about starting enterprises in the newly acquired countries. One of the schemes, plans for which the Philadelphian is now working upon, is a 250 ton ice plant to be erected at Baracoa. There are, he says, a number of other projects on foot, but it will require personal observation in both the islands before they can be inaugurated. Mr. McLaughlin has been furnished with letters of introduction to the respective United States authorities in each of the countries by Secretary Alger and Secretary of the Navy Long. He will be gone at least three months, and it is possible that his absence may be prolonged to six months.

Mrs. Julia Davis has made application for the place of conductor on the Terre Haute Street Railway, and has been making a study of the duties required, spending all the extra money she could spare in taking rides over the line watching the operations of conductors and motormen. One of the conductors in speaking of the applicant to a reporter said: "Mrs. Davis has been on my car, I might say, a hundred times. Only Monday or Tuesday night she was on my car and kept me busy answering all kinds of questions. I understand that she is writing a book which will be called 'Dandy Dan, the Street Car Motorman,' and her trips over the line is to catch phrases to be used in the book. However, I have been told that she intended to make application for the position of conductor. I believe she would make a good one, as she now seems to understand the duties I think she would be able to keep a trolley on the wire and collect fares without making a mistake. Don't know how she would get along with some one who would refuse to pay his fare or insisted on getting change when he had not paid a cent. Guess the boys would all treat her right, and she might be a drawing card for the company for several weeks."

RECENT COMPANY ELECTIONS.

Globe Street Railway Company, Fall River, Mass.—Directors: Edward N. Gibbs and Charles L. Hubbard of Norwich, Conn; John N. Beckley and T. J. Nicholl of Rochester, N. Y; Benjamin Strong of New York; Marcus G. B. Swift, Frank W. Brightman, Robert S. Goff and Herbert H. Read of Fall River.

Park & Falls Street Railway Company, Youngstown, O. —President, S. C. Grier; vice-president, Joseph Hastings; secretary and treasurer, C. W. Dallinger, all of Pittsburg, Pa.; directors: the officers and T. H. McAfee and John Murphy of Pittsburg, and W. H. Park and H. G. Hamilton of Youngstown.

People's Electric Railway Company, Sandusky, O.—Directors: George H. DeWitt, George Feick, C. L. DeWitt, William H. Gilcher, Jacob Kuebler, Daniel Kunz, A. W. Proutt, Frank Stang, T. B. Taylor, John Geideman and Thomas Wood.

COMMERCIAL PARAGRAPHS.

The attention of manufacturers and exporters who receive orders from South America is called to the card of The London & River Plate Bank, Limited, for which Mr. Geo. O. Gordon, 70 Beaver street, New York, is agent in the United States.

This institution is considered one of the strongest and most prosperous foreign banking corporations of London. Its sphere of operations is confined to Brazil, the Argentine Republic and Uruguay, with the Government of each of which countries it has financial relations.

The subscribed capital and reserve fund together represent the equivalent of twelve and one-half millions of dollars. For the year ending on September 30, 1898, the shareholders received in dividends twenty per cent. on the paid up capital.

Branches of this Bank are established in the following ports and cities in South America: Para, Pernambuco, Rio de Janeiro, Montevideo, Paysandu, Buenos Aires, Rosario and Mendoza. In all other places of importance on the east coast of South America it is represented by agents.

The Electric Appliance Company's new catalogue of telephone apparatus and telephone construction material, No. 14, is being well received by the telephone trade, and, judging from the orders for telephone material that are being received, is being very extensively used. The Electric Appliance Company claim that they have the most complete catalogue of telephone supplies that has yet been issued and are pleased to supply copies free of charge to the telephone trade.

INVENTORS.—We neither purchase nor sell your patent, but we examine and report on it to you. If it has merit we furnish endorsements of experts that commend it to capitalists—and those who can use it. Correspondence solicited. Fees moderate. Address

EXPERT, care ELECTRICITY.

INCORPORATIONS

The Huntingburg Light & Power Company, Huntingburg, Ind. Capital stock, $4,500.

The Mutual Electric Company, Waco, Texas. Capital stock, $10,000. Incorporators: W. W. Seley, S. W. Slayden, I. A. Goldstein and L. Migel.

The East Chicago Light & Power Company, East Chicago, Ind. Capital stock, $1,500. Directors: George W. Watson, H. N. Haley and M. L. Pike.

The Charleston & Mattoon Electric Railroad Company, Charleston, Ill. Capital stock, $125,000. Incorporators: Forbes Helton, W. R. Williams and W. R. Patton.

The Kirlin-Gray Electric Company, Watertown, S. D. Capital stock, $50,000. Incorporators: William J. Gray, Minneapolis; George A. Gray, St. Paul, and O. M. and Samuel Kirlin, Watertown.

The Trans-Mississippi Electric Light & Power Company, Macon, Mo.—to establish and manage electric light and power stations. Capital stock, $30,000. Incorporators: Col. F. W. Blees, J. F. Schaefer and Charles E. Roel.

The Miller Improved Incandescent Lamp Company—to establish a plant in Arapahoe County, Col. Capital stock, $50,000. Incorporators: Andrew H. Miller, Merwin J. Barnes, Ernest H. Fontaine and Charles T. Linton. Incorporated at Denver.

The Wichita Railway & Illuminating Company, Wichita, Kan.—to equip and operate a street railway system and an electric lighting and power plant in Wichita. Capital stock, $500,000. Directors: Earnest Rambeck, E. L. Mattling, H. G. Landis, W. O. Church and George E. Spalton, all of Wichita.

The Valley Electric Light Company, Valley Falls, N. Y.—to manufacture and sell electricity for the purpose of lighting and heating public and private buildings in Lansingburg, Melrose, Schaghticoke, Stillwater, Valley Falls and Eagle Bridge. Capital stock, $10,000. Incorporators: E. O. Neil, H. Carpenter, Valley Falls, and J. W. Carpenter, Hoosick Falls.

The Fort George & Eleventh Avenue Railway Company of New York City (a consolidation of the North End Street Railway Company, the Fort George & Eleventh Avenue Railway Company and the Fort George Extension Railway Company). Capital stock, $3,000,000. Directors: John T. Little, Jr., Ambrose F. McCabe, Fred C. Garrick, Frank F. Ogston and Sharon Graham of New York, Clement McCumming of Yonkers, Charles A. Gilbert of White Plains, William A. Dibbs of Brooklyn, and D. C. Moorhead of Jamaica, N. Y.

ELECTRICAL PATENT RECORD.

Letters Patent Issued November 22, 1898

ELECTRIC RAILWAYS AND RAILWAY APPLIANCES.

614,575. Conduit and Electric-Current Conductor for Surface Railways. Arthur Petzenburger, Gross Lichterfelde, Germany. Filed March 30, 1896.
614,709. Means for Driving Railway, Tramway or Automobile Cars. Gustave Dupont and Maxime Johannet, Paris, France. Filed Oct. 29, 1896.
614,651. Car-Fender. John D. Hodges, Chicago, Ill., assignor of five-sixths to James Bellew, Frank H. Repetto and Patrick J. King, same place. Filed Feb. 8, 1898.

ELECTRIC LIGHTS AND APPLIANCES.

614,484. Hanger for Electric Lamps. Junius E. Mayo, Belvidere, Ill. Filed June 1, 1898.
614,528. Electric-Lighting Gas-Burner. John M. Anck, Philadelphia, Pa. Filed Oct. 19, 1897.

ELECTRICAL MACHINERY AND APPARATUS.

614,462. Commutator. John R. Grindrod, Lynn, Mass., assignor to the General Electric Company of New York. Filed Feb. 6, 1897.
614,472. Potential-Switch. John D. Ihlder, Yonkers, N. Y., assignor to the Otis Brothers & Company, New York City. Filed Aug. 5, 1897.
614,571. Transformer System and Apparatus. Adolph Muller, Hagen, Germany. Filed July 30, 1897.
614,608. Dynamo-Electric Machine or Electromotor. Eugene Cantono, Pavie, Italy. Filed Dec. 16, 1897.
614,685. Magnetic Cut-Out. Leonard Andrews, Hastings, England. Filed Nov. 29, 1897.
614,794. Circuit Breaker. William I. Crawford, St. Louis, Mo., assignor of one-half to Abraham Cook, same place. Filed Aug. 23, 1897.

TELEPHONE AND TELEGRAPH APPARATUS.

614,677. Switchboard Apparatus, Signal and Circuit. Thomas C. Wales, Jr., Boston, and Frederick L. Rhodes, Winchester, Mass., assignors to the American Bell Telephone Company, Boston, Mass. Filed Nov. 26, 1897.

BATTERIES.

614,539. Secondary Battery. Nathan H. Edgerton, Philadelphia, Pa. Filed Sept. 14, 1897.
614,759. Galvanic Battery. Charles T. Richmond, Cleveland, O., assignor to the National Carbon Company, same place. Filed July 18, 1898.

MISCELLANEOUS.

614,453. Method of Manufacturing Electric Cables. Sebastian Z. de Ferranti, Hollinwood, England. Filed Dec. 28, 1897.
614,474. Transformer Stamping. Dugald C. Jackson, Madison, Wis., and William B. Jackson, Grand Rapids, Mich., assignors of one-half to William D. Packard and James W. Packard, Warren, Ohio. Filed Sept. 27, 1897.
614,572. Method of and Apparatus for Treating Ores. Joseph G. McNutty, New York City. Filed May 7, 1898.
614,597. Means for Conveying Cables, Wires or the Like Through Underground Conduits. John Wrigley, Elmira, N. Y. Filed June 14, 1898.
614,633. Electrolytic Apparatus. Friedrich A. Thum, Newark, N. J. Filed Feb. 8, 1898.
614,725. Apparatus for Constructing Insulating-Blocks. Johann Jungbluth, Cologne, Germany. Filed Jan. 18, 1898.

TELEPHONE AND TELEGRAPH.

Improvement in Telephone Apparatus.

During the past year or two great improvements have been made in apparatus for central telephone exchange offices. The Newark Telephone Company of Newark, N. J., has just installed a new central office equipment that is pronounced by experts to possess novel and astonishing features never before introduced in central exchange offices. It does its work so rapidly that a great deal of time and money is saved, requiring fewer operators and at the same time giving better service. The Newark Telephone Company is an opposition company to the Bell, and we are informed that such is the success of this exchange equipment that the officials of the Bell Company are simply amazed. This exchange is connected directly with 2,100 local subscribers, and also has connections with substations, giving it a total of over 3,100 connections. As the rentals charged by the Newark Telephone Company are much less than those charged by the Bell people, the citizens of Newark are to be congratulated on securing cheaper and more satisfactory service.

The Northern Minnesota Telephone Company, recently organized at Park Rapids, Minn., has completed its lines which connect Park Rapids with Menahga, Latona and Hubbard, and the system is in operation. The company expects in the near future to extend its lines to Badoura, Pine Point and other points in that section. It will also connect with Wadena, where an exchange system will be put in. It is the intention to eventually connect with other systems which connect with St. Paul, Minneapolis and other important points in the State. The head office of the company will be at Park Rapids. The present officers of the company are: A. B. Kerlin, of Freeport, Ill., president; Cyrus Hollinger, of Lancaster, Pa., vice-president; C. F. Moody, of Park Rapids, secretary and treasurer.

The annual meeting of the stockholders of the American District Telegraph Company, Brooklyn, N. Y., was held on the 21st inst. The old officers were elected as follows: Tunis J. Powell, president; David Barnett, vice-president; Henry W. Kilbourne, secretary and treasurer. The directors are Felix Campbell, Tunis J. Powell, M. N. Packard, William B. Davenport, William M. Van Anden, David Barnett, Clement Lockitt, James W. Ridgway, John A. Nexsen, Stephen Valentine, C.S. Dunning, Thos. Clark, Jr., James F. Pierce.

The Boston *News Bureau* states that the Erie Telephone Company, which recently gained control of the Union Telephone Company in Minnesota and all the independent lines in the Western Electric Telephone Company's system, now proposes to reorganize the companies composing the system by combining them all into one company with a capital of $500,000. The Boston paper says that companies owning nearly 4,000 miles of toll lines have virtually consented to come into the company. These companies all use the Bell instruments and have contracts with the Northwestern Exchange Telephone Company (Erie) and the Iowa Telephone Company.

The Central Commercial Telephone Company, recently organized in Pennsylvania, will open an exchange in Bellefonte in a few days. The company proposes to reach every town in Center, Clinton, Union, Clearfield and parts of Blair and Huntingdon counties. Subscribers can talk to any place in these six counties and Lycoming without extra charge. The rates to be charged will be $1.50 and $2 per month less than those charged by the Bell company. A lively competition is expected.

E. C. Spalding, temporary receiver of the Augusta Telephone & Electric Company, visited the exchange of the company in Augusta a few days ago in company with W. Robinson, who represents the New York creditors, for the purpose of investigating the situation. They found a number of applications for telephones which the management had not been able to put in. The company's directory of subscribers contains this inscription on the back:

"Our automatic switches
"Have no beaux,
"They don't chew gum,
"Giggle,
"Get saucy,
"Tired or sleepy,
"And they are not at all interested in your affairs."

At a meeting of the North & West Branch Telephone Company at Shamokin, Pa., on the 22d inst., it was decided to construct the proposed line between Williamsport, Montoursville and Montgomery to connect with the Shamokin Valley Company's line. The contract was awarded to W. D. Bearnard, of the East Telephone Construction Company, and work will be commenced within thirty days. It will cost about $100,000.

Long Distance Telephone Extension.

President Glidden of the Erie Telegraph & Telephone Company was at Galveston, Texas, on the 15th inst., when word came to him that the gap between Pine Bluff and Helena, Ark., was completed. "This," he said to a reporter of the Galveston *News*, "gives us a continuous telephone circuit extending from Galveston to Bar Harbor, Me., 2,600 miles. It is the longest in the world. Several talks were had to-day with northern points, but the line will not be opened for business until some time in December, as several important electrical transpositions must be made, together with the transferring of way stations, that a through circuit may be established. The circuit consists of a No. 8 copper metallic and runs via Dallas, Paris, Texarkana, Pine Bluff and Helena, where it is cabled across the Mississippi river to Lula, thence on to Memphis. At Memphis connection is made with St. Louis, Chicago, Omaha and all long distance points in the United States. The most northern point is Grafton, N. D.; western point, Omaha, and eastern point, Bar Harbor, Me. There will be no difficulty in talking with New York, Boston and other points as soon as the electrical conditions are perfected.

"It was about twenty-two years ago," continued Mr. Glidden thoughtfully, that Prof. Graham Bell communicated with me by telegraph, asking if a wire of our company could be used for an experimental test of the telephone between Boston and Manchester, a distance of fifty-eight miles. I was then manager of the Atlantic and Pacific Telegraph Company at Manchester, N. H. The test was arranged and it was a success, but we telegraphers were so skeptical regarding the workings of the telephone that for a moment we, unknown to the professor, broke the circuit, and of course the 'sound' ceased. After restoring it, the sound resumed, but even then little did we think that in twenty years we would be able to talk over the wire across the country and from Galveston to New York."

The municipal council of Shanghai, China, invites tenders for a concession for a period of thirty years for the exclusive right of establishing and working a telephone system in Shanghai. Plans may be seen and particulars obtained upon application to Blackall & Baldwin, 39 Cortlandt street, New York, or to Charles Mayne, municipal engineer, Shanghai. Tenders must be sent in not later than the 31st of March, 1899, to J. P. O. Bland, secretary of the council, Shanghai.

The Denver (Col.) *Republican* states that a new telegraph line is to connect Fort Grant and Carlos via Dunlap, Deer Creek, Davis, Lynch and Eureka. The route of the projected line crosses the Graham mountains, a distance of 50 miles. It is to take the place of the old military telegraph which ran through a sandy valley between Fort Grant and Carlos, requiring constant repairing.

John O. Barclay, formerly of Greensburg, Pa., has been appointed electrician of the Western division of the Western Union Telegraph Company, succeeding Charles H. Summers, deceased.

Messrs. Fuller & Perkins of Grand Rapids, Mich., are organizing a stock company to establish a complete telephone exchange to cover Mason, Oceana and Manistee counties, Mich.

The Home Telephone Company of New Albany, Ind., is arranging to have a connection with a telephone line to Indianapolis and intermediate points.

The Western Telephone Construction Company of Chicago has certified to a decrease in the number of directors from seven to five.

The Queen City Telephone Company has been organized at Charlotte, N. C., with J. A. Helvin as president and A. G. Brenizer as treasurer.

Henry Biederman, who recently obtained a telephone franchise at Paducah, Ky., is organizing a company to install a system.

New Companies Incorporated.

The Williams County Toll Line Company, Bryan, O.—to operate a telephone line. Capital stock, $30,000.

The Citizens' Telephone Company, Spencer, Ia. Capital stock, $10,000. Incorporators and directors: O. E. Sully, William Flindt, Ackley Hubbard, C. J. Mikish and J. F. Green.

The Northern Minnesota Telephone Company, Park Rapids, Minn.—to construct a line between Park Rapids and Waldena and in other parts of the State. Incorporators: Charles F. Moods, F. A. Vanderpool, Henry F. Witter of Park Rapids, A. B. Kerlin of Freeport, Ill., and Cyrus Hollinger of Lancaster, Pa.

ELECTRICAL SECURITIES.

The subjoined quotations of Electrical Securities dealt in at the leading commercial centers are compiled from special reports received by ELECTRICITY from a variety of sources. The utmost care is exercised in their collection and preparation, and every effort is made to secure accurate and reliable information. The management of this journal will esteem it a favor to have brought to their attention any inaccuracies readers may discover in these columns.
